Preface

The Commodore 64 User's Encyclopedia is your one definitive reference book for your Commodore 64 Computer. By deciding to own it, you have made an investment in your computing future. It will save you hundreds of hours by bringing material from many sources into a single, easy-to-use, alphabetical reference handbook.

Much of the material is not available anywhere else. Here you will find the essential background material you need to answer your questions and solve problems on the Commodore 64 Computer.

Your *User's Encyclopedia* guides you through machine operation, BASIC programming, and what's available in software and hardware. Your *Encyclopedia* will quickly pay for itself through product information alone. And it is a comprehensive source of information about the whole area of microcomputers. The entries are short, clear, self-contained, and understandable. Should you desire additional information, hundreds of cross-references point you to related entries in the *Encyclopedia*. You will find it the most frequently used and most highly treasured book in your personal computer library.

While your *User's Encyclopedia* was written in simple language so beginning users can understand it, you will continue to find it indispensable as your knowledge of computers grows. It does not offer a detailed coverage of the internal electronic details of the Commodore 64 Computer. It does, however, provide a complete reference on BASIC programming, general operation of the computer and its accessories, and available products.

You will usually use your *Commodore 64 User's Encyclopedia* as a quick reference source. You will probably keep it right by your computer, instantly available when you encounter difficulties or want a more complete understanding of what your Commodore 64 Computer is doing. You will also enjoy just browsing through its many short, easy-to-read entries. This will allow you to easily and casually increase your knowledge of the Commodore 64 Computer, and microcomputers in general. *The Commodore 64 User's Encyclopedia* was produced for you by Gary Phillips & Associates. Gary Phillips & Associates also provides *User's Encyclopedias* for the IBM PC, Apple, Atari, TI-99, and many other personal computers. *The Commodore 64 User's Encyclopedia* will serve as your first reference source for most questions. Manuals from Commodore and other books provide a valuable backup to the *User's Encyclopedia*—when you have time to explore a topic in the traditional book presentation. But when time is pressing and you want information fast, you will rely on *The Commodore 64 User's Encyclopedia*. *The Commodore 64 User's Encyclopedia* is organized alphabetically, with numbers and special symbols following "Z." Here are some special pointers for understanding the format of the *Encyclopedia*:

Variable types in various statements and commands are placed between arrow brackets. For example, <line number> means you would use a specific line number from your BASIC program. Similarly, <variable> indicates any variable you are using in your program. For example, the statement to display a variable's value is PRINT <variable>. To print out the contents of the variable Count, you would replace <variable> with Count, giving PRINT Count. Parentheses () around an item in a command or instruction should be typed by the user at the keyboard. However, brackets [] indicate only that the enclosed material is optional; these brackets should not be entered into the computer. Also, q.v. is used after a word or phrase to direct you to other entries that you may want to see for additional information (q.v. from the Latin quo vide, "which see"). The names and addresses of all software and hardware manufacturers are listed alphabetically in the Vendors List at the end of the book.

We have made every effort to make your *Commodore 64 User's Encyclopedia* complete, accurate, and up-to-date. The descriptions of products are identified by an "" following the product name. These may be

either reviews or brief descriptions to help you find products you may want and acquire further information. You will need to check with the manufacturer or a retail outlet to verify the suitability of the product for your needs and to determine its price and availability. Similarly, you should verify any technical information in the *Encyclopedia* before relying on it for a major decision. Neither the authors, Gary Phillips & Associates, nor The Book Company will be liable for any errors or omissions in the *User's Encyclopedia*. If you should find an error, omission, or have any suggestions for improvements or additions to future printings or revisions of *The Commodore 64 User's Encyclopedia*, please write or call:

A Codes. ASCII = 65, CBM ASCII = 65 or 193, HEX = 41. a—ASCII = 97, CBM ASCII = 65 HEX = 61. Screen code = 1 or 65. See CBM ASCII.

A Diagram symbol for the Accumulator. Also stands for Address line, and the hexadecimal sign for the decimal integer 10: A base 16 = 10 base 10 = 12 base 8 = 1010 base 2.

A In machine architecture, the symbol A refers to Accumulator.

Å Symbol for angstrom, equaling one billionth of a meter (one nanometer).

A: CP/M keeps an internal record of which disk drive is currently considered the "default disk" or "default drive." When you start a CP/M session, the default disk is always A. To change the default disk to B, enter B: To go back to A as default, enter A: To determine which is the default disk drive, look at the prompt (A> or B>) from CP/M. The CP/M prompt itself specifies the default drive (A> for drive A on the left, B> for drive B on the right). See CP/M.

A> CP/M. A> is a prompt from the disk operating system indicating that the drive A is the current default drive. This prompt is displayed on the screen when CP/M is ready to accept a command from the keyboard. This may occur either when CP/M is first started up, at the completion of any command when A is the default drive, or when the user returns to drive A with the command A:. The disk directory is read only during the initial reference to the disk. Every time a disk is changed in the drive, a warm start should be performed on the system to enable CP/M to read the new disk directory.

A Dollar and Change* Students create change for imaginary customers. Cassette. Micro-Ed.

Abort The process of ending a program which has encountered an error. "Abort" returns the control to an operator or operating system.

ABORT CP/M. Command used to halt the execution of a program. The format is:

ABORT<program>

<program> is the program to be aborted, specified in the argument.

See also CP/M Commands.

Absolute Addressing Mode See Addressing Modes.

Absolute Value This term describes the value of a number expressed as a positive number, denoted by enclosure in vertical bars (|). Thus, if a number is positive or zero, then $|x| = x$. If x is negative, then $|x| = -x$.

A-bus The primary internal source-bus to the arithmetic logic unit in any processor.

AC See ACcumulator.

Access Time The time it takes to get a byte of information from memory.

Accounts Receivable and Payable* Can be used to create a posting system for accounts receivable or payable, as well as to print the resulting information. Disk; printer required. Powerbyte.

Accounts Receivable/Billing See Management Accounting Systems.

Accumulator This register is located on the microprocessor. It is used to transfer data and to receive the results of logical and arithmetic operations during the execution of Machine Code. All data passing through the microprocessor invariably passes through the accumulator.

ACK ACKnowledge character in ASCII, a 06 base 16. ACK is used in communications (on some computer systems) to complete a handshaking sequence. The ACK signal indicates that the information has been accepted.

Acoustic Coupler A mechanical instrument for connecting the telephone handset to a computer through a modem. The data is converted to tones—usually audible—for transmission over the phone lines.

ACPTR • Address Notation

ACPTR The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFA5, ACPTR will move one byte of data from the serial bus to the accumulator using complete handshaking. The TALK and TKSA kernal routines must be executed prior to using ACPTR to establish which device will be sending data. The READST routine can be used to return the status word and reveal any errors encountered in the routine.

Across the Plains* A historical teaching game in which two players race across the nation in search of California gold. Score is cumulative from section to section. Package of four programs for ages twelve and over. Cassette. Micro-Ed.

A/D Pronounced "A to D." Analog to Digital. Conversion from a sensor's analog voltages and currents to the digital representation used by computer systems. The computer can then process data directly from the external world.

ADC ADd with Carry. An Assembly language instruction for the 6510 that adds the contents of a memory location or literal to the contents of the accumulator plus the carry bit. The result of the addition is placed in the accumulator. The result affects the sign bit, the overflow bit, the zero bit, and the carry bit. The argument addressing mode can be immediate, zero page, zero page X, absolute, absolute X, absolute Y, (Indirect X), or (Indirect) Y. The instruction can be used to add either decimal or binary with the appropriate bit set. See Machine Language Programming.

Address The address of a byte of data refers to its numerical location in memory. The position of a byte in memory is expressed by a number. In the Commodore 64, the address range is from 0 to 65535. The address is used in programs to alter the content(s) of a specific memory location as well as for retrieving contents from a specific memory location. Often the hardware functions are controlled by addressing specific bytes in memory.

Many of the functions performed by the Commodore 64 are memory mapped. Hardware as well as software can be controlled simply by moving data to a particular address. Moving a number corresponding to a color to address 53281 will automatically change the color of the entire screen. Data from an address can be viewed on the screen using a PRINT PEEK (address) command. Addresses are referred to in BASIC commands in decimal (0 to 65535). In Machine Code instructions, addresses are referred to in hexadecimal (0000 to FFFF). See also Hexadecimal, Memory Map.

Address Bus Coming from the microprocessor of the Commodore 64 are 16 separate lines referred to collectively as the address bus. Since each line can either be in a 1 state (with 5 volts on the line), or a 0 state (with 0 volts on the line), there are 65536 different combinations. Each combination is a specific address. All the RAM and ROM chips as well as the interface chips are connected to the address bus.

Each separate combination or address connects one byte from one of the chips mentioned above with the data bus. That byte may be read onto the data bus or written from the data bus, depending on the control signals. If a different combination or address is turned on, the data bus is then connected to the new address. In this way data can be moved from one device to another. When information is POKED into an address, the number entered by the user is placed on the accumulator of the microprocessor. The address lines are set according to the address specified by the user, and the number from the accumulator is moved to the data bus

Address Mark 8-bit code placed at the beginning of specific fields on a disk track, such as the index, identification, data, or deleted data.

Address Mite 2* Will help you maintain files of names and addresses for easy review, editing, and sorting by name/zip. You can perform searches by key or word. Nelson Software.

Address Notation For the Commodore 64. The conventional notations for representing the position of a byte in memory (Address) are decimal (base 10) and hexadecimal

(base 16). The hexadecimal numbers are preceded by a \$. See also Decimal, Hexadecimal.

Address/Phone List Software See Address Mite 2; Deluxe Addresser; Ma Bell; Mailfile; Mailing List; Mailing List—Home/Business Program; Mailing List, The; Mailman, The; Mini Jini; Phone/Address List Software; Phone Directory; TOTL Software.

Addressing Modes Many Assembly language instructions perform operations on operands. The location of the operand is specified in the instruction in a number of different ways. Addressing modes are the ways those locations can be identified.

Immediate mode: In the immediate mode the operand itself is listed in the instruction. An example would be: Load the Accumulator (LDA) #34 in which the number 34 would be loaded into accumulator.

Absolute mode: In the absolute mode the operand is found at the address that is listed in the instruction. An example would be: LDA \$2500 which would load the number located at address \$2500 into the accumulator.

Zero page mode: In the zero page mode the operand is found in the address listed in the instruction. However, the address listed must be in the first 256 bytes of memory (zero page). LDA \$09 would load the value located at 0009 into the accumulator.

Absolute X mode: In the absolute X mode the address listed in the instruction is added to the value in the X register. The sum is used as the address to find the operand. LDA \$2500, X loads the value located at address (2500+X) into the accumulator.

Absolute Y mode: In the absolute Y mode the address listed in the instruction is added to the value in the Y register. The sum is used as the address to find the operand. LDA \$2500, Y loads the value located at address (\$2500+Y) into the accumulator.

(Indirect X) mode: In the (indirect X) mode the zero page address listed in the instruction is added to the number in the X register. The sum is used as the address of the first of two consecutive bytes whose values are used to calculate the address of the operand. LDA (\$09,X) takes the value located at address (\$0009+X) and the value of the next byte in memory to make a new address. This new address contains the value to be loaded into the accumulator. The Commodore 64 Programmer's Reference Guide calls this mode "Indexed Indirect Addressing." This addressing mode is generally referred to as "Relative."

(Indirect) Y mode: In the (indirect) Y mode the value of the zero page address listed with the instruction contains the low byte of a second address. The zero page address +1 contains the high order byte of this second address. This second address is then added to the Y register to find the true address of the operand. If the Y register contains \$02, address \$09 contains \$03, and address \$0A contains \$25, then LDA (\$09), Y would load the byte located at address (\$2503+2). The Commodore 64 Programmer's Reference Guide calls this mode "Indirect Indexed Addressing." This addressing mode is generally referred to as "Relative."

Adhesive Tab A disk is write-protected if the write-protect notch is covered over with an adhesive tab. The notch is located about one inch down on the left hand side of the disk (when viewed from the top with the disk in the drive insertion position). Attempts to alter the contents of a write-protected disk result in an error message:

"WRITE PROTECT ON"

You are allowed to use files, load them, or copy from the write-protected disk. The purpose of these limitations is to prevent accidental loss of the only copy of programs or data.

It is a good practice to put an adhesive tab (supplied with boxes of disks) over the write-protect notch of any important disk before you back it up. Then if you ask for the backup in the wrong direction (from the destination disk to the source disk), you will get a second chance to make the backup rather than losing your data.

Adjective* Answer questions and hit the RETURN key to grab points going by in a box in the upper left-hand corner. Get the question right, and the number of points you landed on will be added to your score. Get the wrong answer, and the number is subtracted from your score. Ideal for elementary ages and up. Cassette. Micro-Ed.

Adventure Pack I* This series contains three programs: Computer Adventure, Moon Base Alpha, and Jack & the Beanstalk. Cassette. Victory Software.

Adventure Pack II* This series contains three programs: African Escape, Hospital Adventure, and Bomb Threat. Cassette. Victory Software.

Adverbs* Learn about the adverb by definitions and examples, then test yourself and view your performance. Typing in a question mark (?) displays the answers you missed. Good practice for students in elementary school and up. Cassette. Micro-Ed.

Agreement of Subject and Verb* Race a steam engine against the computer by choosing the correct answers to the blanks in nine to thirteen sentences. Program has a bank of thirty-two different problems. Receive a performance summary at end of the race. Cassette. Micro-Ed.

Algorithm A mathematical or logical process that will return the solution to a given problem. First a problem is stated; then an algorithm is developed for its solution. The solution steps are then flowcharted, and the program is developed from the flowchart.

Allocation of Space Assigning particular areas of memory (internal, disk, etc.) to particular files, programs, or functions. Allocation is sometimes done by a programmer, sometimes automatically by a program such as the Disk Operating System (DOS).

On the 1541 disk drive, each track and sector number used by a file is recorded on a special space on disk called the Block Availability Map. When a file is to be stored on disk, the controller of the drive looks at the Block Availability Map to see if the next sector is free. If it is, the block from the file is moved to that sector, and an update is made in the BAM.

Alpha Help • Antonym Machine

On the Commodore 64, BASIC programs are allocated memory from address 2048 to 40959. The computer actually looks at a pointer located at addresses 43 and 44 to know where to start entering BASIC lines and begin storing data at that location. This pointer can be changed to load BASIC in other locations.

Special sections of memory on the Commodore 64 have both a ROM byte and a RAM byte at the same address. The microprocessor can switch between them to allocate more space. Address A000 to BFFF contains BASIC ROM and RAM, E000 to FFFF contain KERNAL ROM and RAM, and D000 to DFFF contain the character ROM and I/O registers.

Alpha Help* Audio and visual aides help teach four- to six-year-olds the ABCs, giving a final report on ability. Cassette. Comm*Data Computer House.

Alpha Test Site vs. Beta Test Site A test site helps the originators of a hardware or software product test it in a real-world situation.

Alpha test is usually performed by a few companies or individuals who realize that their product is incomplete or may have flaws. Alpha testers often are internal to the originating company or otherwise closely related.

There are more Beta test sites. They expect the product to be complete and correct, and agree to test it in a real world production situation. If errors are discovered, the originators ordinarily attempt to fix them rapidly so the Beta sites can stay "on the air" with the new product. If numerous or serious bugs are found, the product may have to go back to alpha testing until an improved version can be presented for another round of Beta testing.

Alphanumeric A set composed of alphabetic, numeric, and special characters.

Alterable Memory The internal memory of the Commodore 64 is comprised of RAM and ROM. The ROM chips have set patterns on each byte of memory that cannot be changed. When power is supplied to the chips, those unalterable numbers are available to the computer.

RAM chips contain random values. When power is supplied to them, they can be changed by the operating system or the user.

Mass storage media also contain alterable memory. Disks and cassettes can be written to save data from the computer. If there is no write protection on the disk or cassette, the same disk or cassette can be written to again and again.

Alternating Current Any signal not constant is considered alternating current; however, this term usually means that the current continuously changes (alternates) polarity.

ALU See **Arithmetic Logic Unit**.

Amortizer, The* Now you can print your own amortization schedules and review principal and interest totals. Disk; printer required. Powerbyte.

Ampere Measurement of electrical current: the actual number of electrons moving past a stated point per second.

Amplifier A device or circuit that increases the power or strength of a signal.

Analog An electrical signal with a continuous range of voltage or current values. Used in contrast with digital.

Analyser/Analyzer Any device that checks or regulates a component, board, or system and presents the data for review.

AND A logical operator used in Boolean operations. The result of an AND operation is 1 only if the value of the two bits tested is 1.

The format is:

<expression> AND <expression>

Example:

20 IF A=B AND C=3 THEN GO TO 100

AND BASIC. Term for a logical procedure defined by the rule: If A and B are 1, then C is 1, other wise C is 0. For logical situations, such as the conditional test in an IF statement, substitute TRUE for 1 and FALSE for 0. For example:

```
10110111
10000100
-----
10000100
```

AND—Assembler Instruction An Assembly language instruction for the 6510 that performs the logical AND on the contents of the accumulator and the contents of a memory location or literal. The result of the AND function is placed in the accumulator. The result affects the sign bit and the zero bit. The argument addressing mode can be immediate, zero page, zero page X, absolute, absolute X, absolute Y, (Indirect X) and (Indirect) Y.

Animal Zap* A shoot 'em-up program that includes two games: Animal Zap and Number Zap. Cassette. Comm*Data Computer House.

Animation The use of movements in graphics to simulate action. In most computers, animation is created with multiple graphic displays in succession. The microprocessor looks at one RAM area for its screen display and is then commanded to look to another and so on, creating the illusion of movement. The Commodore 64 has a sprite system that facilitates and greatly simplifies animation. A sprite is created once and can be moved using specific addresses. See Sprites.

Annihilator* Defend planets against invaders in this Machine Code program. Cassette. Victory Software.

ANSI American National Standards Institute.

Antonym Machine* This program chooses pairs of words with opposite meanings, shows you one of them, and has you fill in the other. Your performance is evaluated as you go. For elementary level students. Cassette required. Micro-Ed.

Antonym Match* A dozen pairs of antonyms are concealed from sight. Two players, in turn, choose two sections to look at and try to find a set. Good practice for fourth through sixth graders. Cassette. Comm*Data Computer House.

APL A Programming Language (APL) invented by Kenneth Iverson. It is used for algorithmic interactive programming.

Apostrophe* After being introduced to the proper use of apostrophes, the student is quizzed on the material and a final report on ability is given. Ideal practice tool for elementary students and older. Cassette. Micro-Ed.

Append To add to the end of a character string, list, or file.

Apple Loader* A device that helps transfer programs from the Apple computer to the Commodore 64. It only allows the transfer of BASIC language words, not Machine Code or Assembly language. Once transferred, the program must be modified for use on the Commodore 64. Interdesign, Inc.

Applications Software A software package is a group of computer programs, possibly including data files and documentation, that perform a function or group of related functions on the computer. These are called applications software when the programs are devoted to an end user task. Examples are a word processing package or an accounting package. Systems software packages, on the other hand, facilitate the use of the machinery; these include disk operating systems and program development packages.

Arbitration Management of claims by competing systems or processes for a limited resource. Bus arbitration allocates a system bus among the sub-system components, i.e., the CPU, memory, disk controller, and other external devices.

Architecture The special selection, design, and interconnection of the principal components of a system. In a microprocessing unit this could be the number and function of registers, the instruction addressing modes, and the bus structure and timing.

Arctangent BASIC. See ATN.

Area and Perimeter* A graphic program that uses problems to help students learn area and perimeter formulas. Cassette. Comm*Data Computer House.

Area of a Rectangle* Helps elementary students increase their understanding of the formulas for finding the area of a rectangle. Features excellent graphics and different levels of difficulty. Disk or cassette. Microcomputer Workshops.

Argument Data passed from one process or program to another process or program. Similar to a football pass, except that one or more bytes of data replaces the football (and the receiver is a program). The sender may be a program or a person typing the data onto a command line

to be "passed" to a program. The two most common examples would be DOS passing parameters from the command line to a program (see Relocating Loader) and a BASIC program passing variables to a subroutine.

Arithmetic Logic Unit (ALU) The element in the central processor which performs the basic data manipulations in the central processor such as add, subtract, complement, negate, rotate, AND and OR.

Arithmetic Operations Arithmetic operations are performed on a priority basis on the Commodore 64. When executing calculations on a particular line, first priority goes to performing exponentiation from left to right. Once those calculations have been done, multiplication and division are performed from left to right on the line. Finally, addition and subtraction are performed. Parentheses can be used to bypass the normal hierarchy of operations.

Arithmetic Statement An instruction specifying an arithmetic operation.

ARQ Automatic ReQuest for repeat. In telecommunications, a device capable of determining whether it has correctly received information transmitted from another source may automatically request a repeat transmission.

Array A group of data items identified by one name. Each item can be located by its subscript; subscripts are a set of numbers indicating the placement of each item in the group.

Array BASIC. An array is a list consisting of identical TYPE data elements. A reference to an array in a program is ordinarily made by the name of the array and the index of the specific element in the array. For more information on Arrays in BASIC see DIM statement.

Arrays BASIC. See DIM.

ASC BASIC Numeric Function. Returns the Commodore ASCII code (a number between 0 to 255) for the first character in the string <string>.

The format is:

ASC (<string>)

<string> is a string constant or variable.

An example is:

```
READY 10 X$="STRING" 20 PRINT ASC (X$) RUN 83
READY
```

In this example the ASCII code for "S" is 83. "S" is the first character of the string X\$. If X\$ is null, the system responds with an error message:

?ILLEGAL QUANTITY.

For a listing of the ASCII codes see ASCII and CHR\$ CODES.

ASCII Code to Characters • ATN

ASCII Code to Characters BASIC. See CHR\$.

ASCII Codes for Characters BASIC. See ASC.

ASL Arithmetic Shift Left. An Assembly language instruction for the 6510 that shifts the contents of the accumulator or of a memory location to the left one bit. A 0 moves onto the rightmost bit and the leftmost bit moves into the carry. The result of the shift is left on the accumulator or the memory location of the shift. The result affects the sign bit, the zero bit, and the carry bit. The argument addressing mode can be zero page, zero page X, absolute, absolute X, or the argument can be A for accumulator.

ASR Automatic Send Receive. A terminal having not only a keyboard and printer, but also an automatic reading and recording device, such as a cassette tape unit or a paper tape reader and punch.

Assembler Synonym for Assembly, a programming language. See Assembly language.

Assembler 64* A software product for the Commodore 64 with a number of programs for writing, editing, assembling, and loading assembly language programs. The editing program lets the user enter assembly language programs with the same screen editing capabilities as in BASIC. The assembler program converts the program into Machine language and indicates any errors in syntax or compiling. An option for printing is included. A monitor program comes with added capabilities for debugging programs. The package presumes the reader already has some understanding of Assembly language programming, but is an excellent package for Machine Code development. Printouts and can be dumped to most Commodore 64 compatible printers. Disk. Commodore.

Assembly Language Or Assembler language. A programming language closely related. Usually an Assembler program is longer and more difficult to understand (and to code) than a BASIC program to perform the same process. The tedious and time-consuming nature of Assembler programming led to the invention of "high-level" languages, such as BASIC, FORTRAN, COBOL, and Pascal. These languages greatly abbreviate the description of the work to be done by the computer. A complex translation process is required to turn the high-level program into a Machine language program that the computer can use. This translation process is time consuming and usually results in a Machine language program that runs many times slower than a corresponding program written in Assembly language.

The compiled program is also usually many times larger than a corresponding program written in Assembler. Why is this? Because higher level languages simplify the programmer's job by using very general program procedures which can handle all possible circumstances in which the statements might be used. Since, for a particular program, only a small fraction of this generalized code is needed, much of the code produced by the compiler is superfluous. The information required to specify whether or not it is needed is exactly what was left out in simplifying

the higher level language.

Interpreted languages (such as BASIC) have an additional performance disadvantage. They do the translation of higher level source code into executable Machine Code every time the program is executed, rather than only once. Assembly language programs can run much faster, use less memory, and access more special machine level functions such as direct I/O devices, than BASIC or other high level languages. Assembler is popular with software houses for writing programs that must run very fast (action games or programs to run fast devices such as disk drives, etc.). But because Assembler is harder to code, few individual users write programs in Assembler. Those who do, ordinarily write only selected time-critical or highly specialized routines. More commonly, a program written largely in, for example, BASIC may use a short section of code written in Assembler to do one particular time-critical or memory-size critical task. The Assembler code will be called as a subroutine by the BASIC program.

In summary, Assembly language is a highly technical language more adapted to the needs of the processor than to the needs of the user. It is invaluable when speed or memory size is critical, for highly specialized applications and for commercial software development. But for most users it is not practical to use Assembler as a regular programming language. They can rely on commercial software packages or write programs in a high level language such as BASIC. If an Assembly language program or subroutine is required for your application, paying an experienced Assembly language programmer would be considered an alternative to learning Assembler. But if you enjoy getting to the nuts and bolts of the computer, Assembly language is the quickest route to the inside workings of the computer.

Assembly Language Debugger* Contains all the standard debugging features. Includes windowing, steps, break-points, super-complex conditional breaks, patch, compiled BASIC-like language, and more. Disk or cassette. Pterodactyl Software.

Assignment Giving a value to a variable. In BASIC, a simple assignment would be:

```
LET X=5
```

This assigns the value 5 to the variable X.

Asynchronous An event or device which does not have the same timing as the central processing unit.

At Home Inventory* Keep an inventory of all your personal property in case of an emergency. Record serial number, descriptions, purchase price, and other information. Powerbyte.

ATE Automatic Test Equipment. These devices and/or programs (usually ROM resident) automatically perform routine checks on equipment. The tests may occur on a time scheduled basis, or in response to an event, such as powering on or resetting the system.

ATN BASIC Function. Returns the ArcTanGent of <X>. The format is:

Atom • Auto Clock

$\langle v \rangle = \text{ATN}(\langle x \rangle)$

$\langle x \rangle$ may be a numeric expression of any numeric type. The evaluation of ATN is always performed in single precision. ATN returns the angle whose tangent is x , θ measured in radians in the range $-\pi/2$ to $+\pi/2$, where $\pi = 3.141593$. To convert radians to degrees, multiply by $180/\pi$.

Atom* Includes tables, graphics, and a book on various aspects of the atom and its composition to aid in learning molecular principles. A quiz picked arbitrarily from a list of thirty follows completion. Good practice for science students. Cassette. Micro-Ed.

Atoms* Learn molecular structure and atomic composition of salt with graphic visuals. Includes short test after completion. Made especially for junior high school students. Disk. Comm*Data Computer House.

Attack Sound The rate at which the volume of a note rises from the moment it is first struck to the moment it reaches maximum value. Attack is a component of the envelope that the SID chip of the Commodore 64 executes for each note.

Attenuation The reduction in strength of an electrical impulse.

Audio/Video Port The Commodore 64 comes with a 5-pin DIN socket in the rear of the computer that serves as an audio/video port. This port can be used for a monitor or an alternate sound system. Except for the 1701 monitor from Commodore, this port is not generally plug compatible with most monitors. It is, however, possible to use an adapter to convert the 5-pin DIN to the RCA jack used by most monitors. Looking at the back of the Commodore 64, you will see that the bottom plug is attached to the ground of the monitor cable and the rightmost socket (LUM) is attached to the video line of the monitor cable. Remember, on a monochrome monitor it may be necessary to change the background color and character color of the Commodore 64 for high resolution. A higher quality sound system can be used by a similar adapter using the far left DIN pin (looking from the back) for the audio and the bottom pin for ground. The user's guide that comes with the Commodore 64 has a pin configuration in the Appendix.

B Codes. ASCII = 66, CBM ASCII = 66 or 194, HEX = 42. b—ASCII = 98, CBM ASCII = 66, HEX = 62. Screen code = 2 or 66. See CBM ASCII.

B B is used as an abbreviation for Bytes when referring to memory, or Baud rate when referring to communications. KB = 1000 bytes or baud (technically 1K = 1024 bytes).

B Bus line. Also: the hexadecimal symbol for the decimal number 11.

B: CP/M—Change Default or Current Disk Drive CP/M keeps an internal record of which disk drive is currently considered the "default disk" or "default drive." When you start a CP/M or BASIC session, the default disk drive is always A. To change the default disk drive to B, enter B:. To go back to A as default, enter A:. To determine which is the default disk drive, look at the prompt (A> or B>) from CP/M.

B> CP/M. B> is a prompt from CP/M indicating that the drive B is the default drive. The prompt also indicates that the system is ready to accept a command from the keyboard. To go back to drive A, enter A:.

B-A Disk Command. See Block-Allocate.

Backfire* An action game in which elementary school students try to destroy the divisors of a set number after defining them. Cassette. Micro-Ed.

Backgammon* The old "you against the computer" game with three levels of difficulty and full color graphics. Cassette; 3K RAM. Star Tech, Inc.

Backplane Also called a motherboard, it is the physical area in a system where the boards plug in. It usually contains the buses of the system either in printed circuit or wire-wrap form.

Backup A backup utility that will copy some copy-protected disks but not others.

Backup Copy A duplicate copy of a program or data stored on a second disk or cassette in case of loss or damage to the original.

Backup Devices See Disk Drive, Cassette.

Backup Disks See Write-Protect, Adhesive Tab.

Bad Data An error message from the Commodore 64 indicating that while a program was set up for receiving numeric data it received string data instead. INPUT #5,A indicates that the data being input from the open file referenced by 5 must be a numeric value. If instead an alphabetic character or word is input a "Bad Data" message will appear.

Bad Sector A sector on the disk which will not read/write data correctly. Usually due to a minor physical flaw in the disk. One or two bad sectors will not seriously affect the disk's use; DOS will mark them as bad and avoid using them. If there are more than a few bad sectors, the disk should be used as a frisbee rather than a device for holding your valuable data.

Bad Subscript An error message from the Commodore 64 indicating that the program encountered an element of an array that is outside the range dimensionalized in the program. If you neglect to dimensionalize an array and you attempt to use more than ten elements per variable you receive this error message. For example, the statement:
FOR X=1 to 20:A(X)=X:NEXT
results in a "BAD SUBSCRIPT" error message if you do not first dimensionalize A(X).

Balancing Chemical Equations* Helps high school students gain experience at balancing chemical equations. The problems increase in complexity as the students progress. Disk or cassette. Microcomputer Workshops.

BAM See Block Availability Map.

Bank The 64K of memory in the Commodore 64 is divided into 4 Banks (sections) of 16K each. The VIC-II chip can only access the memory one bank (16K) at a time for video display information. See also Vic-II, Complex Interface Adapter.

Bar Chart* The bar chart format is available for fast and efficient visual exhibition of arithmetical information. Disk; printer required. Powerbyte.

Bar Code The consumer product information code. The bars of various thickness found on many store items represent a bar code that is unique for each product. By reflecting light off this bar code into a photoelectric cell, the bar code is converted into bytes of information in a computer. The computer can then identify the product, its price, number of units left, etc.

Bar Graph* Helps elementary students to better understand bar graphs and the type of information they contain. A review is offered at the conclusion of the practice. Cassette. Micro-Ed.

BASE • BASIC Statements

BASE Alternate business name of Bay Area Systems Engineering—Originators of the *Commodore 64 Users Encyclopedia*, *The Vic-20 User's Encyclopedia*, and other information resources for the personal computer user.

Base Register The register which contains the longer part of a two-part Assembly language address. The smaller part, called the displacement or offset, is contained in the Assembly language instruction. The data that the instruction is to operate on is located at the "effective address"—the byte of memory whose address is the sum of the number in the specified base register and the offset number given in the instruction. This method of specifying addresses allows data to be located with fewer bits than would a full, explicit address.

BASF Badische Anillin und Soda Fabrik, a manufacturer of magnetic storage media including disks.

BASIC Beginner's All Purpose Symbolic Instruction Code. A popular computer language invented at Dartmouth for educational purposes. Similar to the FORTRAN programming language, BASIC is easy to use and learn, and is now on almost all microcomputer systems. Some BASICs have just the bare essentials of regular BASIC, which is a form of Dartmouth original BASIC. Super BASICs may have features from other languages. Compatibility problems between various BASICs do exist.

BASIC Compiler Programs written in a high-level language such as BASIC are converted into the Machine Code equivalent by a program called the Compiler. Once compiled, the Machine Code form of the program can be stored and executed at any time with up to 300 times the speed of the original BASIC program. This is different from an Interpreter, which translates or interprets each program instruction as it is executed and every time it is executed. The Commodore 64 has a built-in BASIC Interpreter that converts the "Source Code" (a BASIC program) into an "Object Code" (Machine Code) each time the program is executed.

BASIC—Default or Current Disk Drive CP/M and BASIC keep an internal record of which disk drive is currently considered the "default disk" or "default drive." When you start a CP/M or BASIC session, the default disk drive always is A. To change the default disk drive to B, enter B; or, to go back to A as default, enter A. To determine which is the default disk drive, look at the prompt (A> or B>) from CP/M.

Basic Disk Operating System CP/M. See BDOS.

Basic Input Output System CP/M. See BIOS.

BASIC Interpreter The interpreter is a Machine language program that uses the "source" program as data—a source of instructions or commands to control its execution. The source program in this case is a higherlevel language (BASIC) program that is converted into Machine language (ML) code line by line as the program is executed.

BASIC Interpreter—CBM BASIC Interpreter The Commodore 64 is equipped with an 8K CBM BASIC Interpreter which converts (interprets) Commodore BASIC into Machine language step by step as it executes the BASIC program. The interpreter is located at address 40960 through 49151.

BASIC Prompt Commodore 64 uses READY, a BASIC prompt, which means that the system is ready for the programmer.

All statements on one line, however, should not exceed 80 characters. In the event of an overflow, all the extra characters will be ignored. The line number at left refers to all statements on the line. Here are two examples of multiple statements on one line.

```
40 LET X = 1:REM Comment
50 LET X = 1:LET Y = 2
```

BASIC Variable Names. See Names.

BASIC 2.0 The Commodore 64 utilizes a version of microsoft BASIC 2.0.

Basketball Stats* A statistical management package for basketball players, consisting of three program files on the system disk and an accompanying manual. The files are 1) Customizer—used at the beginning of the season to personalize all reports with the team name, coach's name, and the season year; 2) Stat Aid—a statistical program that will produce at summary reports for single games, season totals, and the team win-loss record; and 3) League Totals—this file allows the coach to print a statistical summary of player performance in league games only. Midwest Software.

Batch Processing A program or a series of programs is run to completion or aborted, prohibiting interaction between the user and the program.

Battery Backup Batteries provide auxiliary power to the processor so that information is not lost during a power failure.

Baud See Baud Rate.

Baud Rate Input/Output Parameter. Rate of data transfer between devices measured in bits per second. For example, the Commodore 64 transfers data through the VIC 1600 modem at a rate of 300 Baud. In addition to the 8 bits transmitted for every byte, there is also a start and a stop bit associated with each byte, thus resulting in a transfer of 30 characters per second.

Baud Rate Generator An oscillator, usually adjustable, providing clock signals for connection of a peripheral. Typical rates are 110, 300, and up to 9600 baud.

Baudot An older communications code, named for the man who invented it, and used for 5-level (hole) teletypewriter and telex machines. Other codes used are ASCII and EBCDIC, which are 8-level codes.

B-bus The second source-bus to the arithmetic logical unit in a 2- or 3-bus processor.

BCC Branch on Carry Clear. An Assembly language instruction for the 6510 that tests the carry bit. If the carry bit is 0 the next instruction performed is found by adding the current address with the signed displacement found in the argument. The displacement must be between -128 and +127. None of the flag bits are affected.

BCD Binary Coded Decimal. A 4-bit binary representation of the 10 decimal digits 0 through 9. Six of sixteen possible codes are unused, requiring the use of a "Decimal Adjust" instruction for correct binary addition. 1 is encoded as 0001, 9 as 1001. Two BCD digits are usually packed in a byte.

BCP Byte Control Protocol. A protocol for communications between two computers or devices. The start of a message is marked by a special character, which is followed by a count of the number of data bytes, and then the data bytes themselves. Also called byte count oriented protocol.

BCS Branch on Carry Set. An Assembly language instruction for the 6510 that tests the carry bit. If the carry bit is 1 the next instruction performed is found by adding the current address with the signed displacement found in the argument. The displacement must be between -128 and +127. None of the flag bits are affected.

BDOS CP/M: Basic Disk Operating System (one of the three functional components of CP/M). It manages disk files, file storage, retrieval, and allocation. See also CP/M.

Bell Laboratories Research laboratories in New Jersey which made many major discoveries in the electronic and computer field, including the invention of the transistor.

Bell Ringer* A carnival atmosphere helps motivate students to learn fractions and their equivalent percent values. Cassette. Micro-Ed.

Benchmark Program A specific program written to calibrate the speed of a computer in a well defined situation, or type of computation, e.g., scientific "number crunching," sorting, or compilation. Benchmark programs are used to compare performance of one computer to another.

BEQ Branch if Equal to zero. An Assembly language instruction for the 6510 that tests the zero bit. If the zero bit is 1 the next instruction performed is found by adding the current address with the signed displacement in the argument. The displacement must be between +127 and -128. None of the flag bits are affected.

Beta Test Site vs. Alpha Test Site See Alpha Test Site vs. Beta Test Site.

Bi-Directional Data flows in either direction on a wire. At each end there are transceivers to both receive and transmit. Common bidirectional buses are tristate or open collector Transistor-Transistor Logic (TTL).

Bi-Directional Printing Alternately printing in either direction. A line printed left to right is followed by a line printed right to left, avoiding a carriage return delay and increasing printing speed.

Bigital Clock* Turn your Commodore into a giant digital clock with twelve and twenty-four hour displays. The format can be changed while running. Micro Software Systems.

Billboard* Use your computer as a promotional tool with a message moving continuously across the screen. Disk or cassette. Micro Software Systems.

Binary Counter Outputs a sequence of ascending or descending binary numbers.

Binary Number An integer as a sum of powers of 2, using a sequence of 0s and 1s. The binary representation for the number 8 would be 1000. This can be computed by taking $(1 * 2(\text{power of 3})) + (0 * 2(\text{power of 2})) + (0 * 2(\text{power of 1})) + (0 * 2(\text{power of 0})) = 8$.

BIOS CP/M: Basic Input Output Operating System (one of the three functional components of CP/M). It facilitates exchange of data and status information between the CCP (Console Command Processor) and a peripheral device. See CP/M, CCP.

Bipolar A technology of integrated circuit fabrication using transistor switching elements based on majority carriers for switching and amplification. See MOS.

Bistable Multivibrator Active elements able to assume either one or another stable state characterize a flip-flop circuit.

BISYNC Pronounced by-sink. Binary SYNchronous Communications protocol. An IBM character-oriented protocol for synchronous transmission of binary-coded data between two devices. Uses a defined set and sequence of control characters.

BIT Compare memory bits with accumulator. An Assembly language instruction for the 6510 that performs a logical AND between the contents of the accumulator and the contents of the memory location specified by the argument. The argument is addressed in zero page or absolute mode. The result does not change the accumulator or the memory location, but if the two numbers compared are identical, the zero flag bit is set. Also, the sign bit of the argument is moved to the sign flag bit and bit 6 of the argument is moved to the overflow flag bit.

Bit A contraction of Binary Digit. A bit is a 0 or a 1. Bits are used in computer systems to code information, instructions, and data. Larger units of bits are: nibbles (4), bytes (8), or words (8, 16, 24, 32, 96 or more).

Bit Map Mode Graphics. Bit map mode in the Commodore 64 allows the programmer to address each bit or pixel on the screen individually, thereby increasing the resolution to 320 x 200 bits in high resolution mode or 192 x 200 in multicolor mode. This mode facilitates creation of highly detailed images or graphics. The bit map mode is turned on by setting bit 5 of the VIC-II control register to a 1 at location 53265 (HEX D011).

Bit-Parallel Data transmission method by which every digit of a binary number is sent over a separate wire simultaneously.

Block Within a logical record, information is stored in units or blocks. On the 1541 Disk Drive a block refers to a group of 256 bytes. It is essentially synonymous with sector

Block Availability Map • Bootstrap

except that a sector is generally associated with a specific location. Block is also sometimes used to mean a collection of logical records, as in blocked records or blocking factor. Block size is usually expressed in bytes.

Block Availability Map A checklist of used blocks on a disk. Physically located on track 18 sector 0 of the disk, it is updated every time a file is SAVED or CLOSED.

When a file is to be SAVED onto disk, the controller checks the BAM to see if there is enough space for the file. If there is enough space, the data is copied onto disk and the BAM is updated to indicate that the space is no longer available.

Block of Memory A series of consecutively numbered bytes in a memory device (usually internal).

Block-Allocate Disk Command. The Block-Allocate command, when sent through the command channel, checks to see if a block on the disk is free to be used. It does not destroy data on the block, but if the block is already in use an error condition will be revealed on the command channel. Used only on random files. The format is:

```
OPEN15,8,15
PRINT#15,"BLOCK-ALLOCATE:"<drive>,<track>,<block>
```

<drive> is the disk drive number. 0 if only one drive.

<track> is the track number on block being checked on disk.

<block> is the sector number of block being checked on disk.

Block-Free Disk Command. The Block-Free command, when sent through the command channel, will change the Block Availability Map (BAM) and thereby make a block that may or may not have data on it available on disk. It effectively scratches that block. Used only on random files. The format is:

```
OPEN15,8,15
PRINT#15,"Block-Free:"<drive>,<track>,<block>
```

<drive> is the disk drive number. 0 if only one drive.

<track> is the track number on disk to be freed.

<block> is the sector number on disk to be freed.

Block-Read Disk Command. The Block-Read command, when sent through the command channel, will move one block of data from the track, sector, and drive specified by the user to a channel assigned by the user. The command is only applicable to random files. The format is:

```
OPEN15,8,15
PRINT#15,"Block-read:"<channel>,<drive>,<track>,<sector>
```

<channel> is an arbitrary channel 2 through 14, previously opened, in which data will be sent

<drive> is the drive number. 0 if only one drive.

<track> is the track number on disk to be read.

<sector> is the sector number of block to be moved.

Block-Write Disk Command. The Block-Write command, when sent through the command channel, will move one

block of data from a channel previously opened to a location on the disk specified by the user. The command is used only for Random Access Files. The format is:

```
OPEN15,8,15
PRINT#15,"BLOCK-WRITE:"<channel>,<drive>,<track>,<sector>
```

<channel> is an arbitrary channel 2 through 14, previously opened by the user, in which data is first entered.

<drive> is the number of disk drive being used. 0 if only one drive.

<track> is the track number on disk where block of data will be sent.

<sector> is the sector number on disk where block of data will be sent.

BMI Branch on Minus. An Assembly language instruction for the 6510 that tests the sign bit. If the sign bit is 1 the next instruction performed is found by adding the current address to the signed displacement found in the argument. The displacement must be between -128 and +127. No flag bits are affected.

BNE Branch on Not Equal to zero. An Assembly language instruction for the 6510 that tests the zero flag bit. If the zero flag bit is 0 then the next instruction performed is found by adding the current instruction to the signed displacement found in the argument. The argument must be between -128 and +127. None of the flag bits are affected by this instruction.

BNPF Representation An older data encoding format for PROM programmers using the characters B = beginning, F = finish, N = negative (1), P = positive (0). For example, the byte 10010110 is represented as BNPPNPNNPF. See PROM (Programmable Read-Only Memory).

Buffer In software, any memory structure provided for the temporary storage of data. In hardware, a device which restores logic drive signal levels in order to drive a bus or a large number of inputs.

Buffer, Printer A printer buffer is a device which connects the printer to the computer and stores any incoming data from the computer into its own memory, thereby freeing the computer for other processing. The data stored in the buffer memory is then fed to the printer. This way the user doesn't waste time waiting for a text or a program to finish printing before he can start processing again. It takes a few seconds for the buffer to download data from the computer and return control to the user. Printer buffers may also be used for connecting modems with computers.

Buffered Parallel Cable & Driver* This interface is compatible with almost any printer that has a Centronics type connection and configuration. It is fully buffered and very reasonably priced. Can be expanded with other Commodore cartridges or disks and comes with good documentation. Micro Ware.

Buffering The delaying and temporary storage of data in a data communications path.

Buffer-Pointer Disk Command. The Buffer-Pointer command, when sent through the command channel, allows you to selectively access individual bytes of information from a random file buffer. Used in random files only. The format is:

```
OPEN15,8,15
PRINT#15,"Buffer-Pointer:";<channel>,<location>
```

<channel> is an arbitrary channel number 2 through 14, previously opened by the user, to send or receive data. Effectively this is a buffer since data in this channel must be moved to or from the disk one block at a time.

<location> is the byte number 0 through 255 within block in channel.

Bug Errors in a program. A programmer must ensure that a program will correctly process all of the types of data for which it is intended. Samples of the data are prepared (test data) and the program is executed using this data (a test run). The program's outputs (reports, screen displays, files, etc.) are then verified to be as specified. An error in the processing logic of a program is called a "bug," hence the terms "debug" and "bug-free."

Byte Byte, abbreviated B, is the storage capacity needed to hold one character (letter, digit, etc.) in computer memory, internal or external. A group of 8 bits is a byte. A thousand bytes is a K byte, abbreviated KB, or simply K. (Actually, 1K = 1024 bytes because this is an even power of 2.) The Commodore 64 has 64K (or 64KB) of internal memory, or 64,000 bytes (to be precise, 64K = 64 x 1024 = 65,536 bytes).

C Codes. ASCII = 67, CBM ASCII = 67 or 195, HEX = 43. c—ASCII = 67, CBM ASCII = 67, HEX = 63. Screen code = 3 or 67. See CBM ASCII.

In addition to upper and lower case letters the Commodore 64 can display a set of PET graphic symbols. When the system is powered on, any letter from the keyboard is in upper case. If a character is pressed in conjunction with the shift key, the graphic symbol to the right of the key is displayed. If the special key is pressed in conjunction with the shift key the display mode changes to lower case. Pressing any key in conjunction with the special Commodore key displays the graphic symbol to the left of the key.

Calc Result* A superior spreadsheet with features not found in similar programs. The screen is formatted into rows and columns. The user can enter numbers, labels, or formulas into any intersection of a row and column. Formulas can perform arithmetic operations on any of the other numbers entered into the spreadsheet. If a number previously entered is changed by the user, all the affected formulas automatically change their values. A spreadsheet can be saved as a "page" and compared against other "pages." Calc Result can split the screen horizontally or vertically so that different pages can be compared simultaneously. A window can be placed on a page to compare a separate page and the window can be split to have four separate "pages" compared at the same time. The formulas can involve addition, subtraction, multiplication, division, or exponentiation. They can determine the maximum or minimum values of a set of numbers. The formulas can utilize the logical functions AND, OR, or NOT, as well as the IF THEN statements. Inequalities such as > or < can be used in formulas. Calc Result can calculate mean values for columns and rows. The spreadsheet can be output to the printer in a number of formats. The user can print just what is on the screen or specify a range of rows and columns to be printed. Output can be varied when the user specifies how many characters he wants printed for each entry. Lists of numbers can be printed as a bar graph with the user entering upper and lower limits for the graph. Calc Result manages this spreadsheet with a cartridge inserted into the expansion port, as well as a work space on disk. Pages can be saved on separate data disks. It is hard to imagine a more complete spreadsheet for the Commodore 64. The documentation is clear and concise. The only item limiting the use of this spreadsheet is the printer. Calc Result is compatible with the 1520 printer plotter or the 1525 printer. Using any other printer can result in unpredictable results. Handic Software AB.

Carriage Return In the program mode of BASIC operation, the carriage return <CR> is used to enter each program line (containing one or many statements, but not exceeding 80 characters). The line is sent to the interpreter to be tokenized and stored in the program. Similarly, when editing a program listing, <CR> is used to replace the existing line with the modified line in the program memory. When in direct mode of BASIC operation, any BASIC statement(s) entered on the screen are executed upon carriage return.

Carry Look-Ahead A circuit which uses partial adders to predict the final carry from propagate and generate signals. Binary addition is speeded up significantly by eliminating the carry propagation delay.

Cash Flow Model* Gives you an instant summary of your financial situation. Disk; printer required. Powerbyte.

Cassette If information from the Commodore 64 is to be saved permanently, it must be transferred from the internal memory to a mass storage device. The C2N Datasette Unit model 1530 from Commodore is one such device. Data is saved sequentially on magnetic tape. Data is transferred at about 50 bytes per second. The cassette has a device

number of 1. The load and save commands are used to LOAD and SAVE program files. Sequential files can be saved after first opening the channel to the cassette. See OPEN command. Ones and zeros are saved on tape using square waves of different lengths. When a program is saved on tape the address in memory where it began is saved into a header on tape. The program can then be loaded in to the exact address from where it came.

Cassette Port The following is a diagram of the cassette port on the C 64:

Cassette LOAD Instruction See LOAD.

Cassette SAVE Instruction See SAVE.

Catch the Rhyming Fish* A fun game for elementary children to recognize rhyming words. For each word that appears at the top of the screen, the child must choose the one that rhymes with it from the three words the fish are towing across the screen. Cassette. Micro-Ed.

Caterpillar 500* You control the progress of a caterpillar as it races around a track trying for the best time. Suitable for elementary children. Cassette. Micro-Ed.

CBM ASCII Alphanumeric characters and symbols are stored in computer memory as numbers. The designers of a computer decide which number will represent which character. One very common standard of representation is the American Standard Code for Information Interchange (ASCII). When a computer uses ASCII values, the upper case letter A is stored as the number 65 and a lower case letter a is stored as the number 97. Commodore deviates slightly from conventional ASCII values. Commodore has a text mode where characters can be viewed as upper or lower case letters and an upper case/graphics mode where letters are viewed only as upper case letters. In upper case/graphics mode (used for entering BASIC programs) the letter A is stored as the number 65. In upper/lower case

mode (used for entering text) the upper case A is stored as the number 193 and the lower case a is stored as 65. Which characters the numbers 65 and 193 represent on the screen depends on the mode during display. To make it even more confusing, the characters represented by the numbers 192-223 are the same for the numbers 96-127. To determine the CBM ASCII value for a character, enter the command PRINT ASC (<x>) where <x> is the letter. To obtain the character represented by a CBM number enter the command PRINT CHR\$(<x>) where <x> is the number.

CCD Charge Coupled Device. A storage device using Metal Oxide Semiconductor (MOS) capacitors. It transfers charge from one cell to another in a recirculating pattern.

CCP CP/M. Console Command Processor is the "intelligent" component of the three functional modules (BIOS, BDOS, and CCP). It is user-interactive (interprets commands typed at the keyboard) and performs internal processing using BIOS and BDOS as sources for status and data information. See CP/M.

CDILP Ceramic Dual In-Line Package. See DIP.

Cell A repeated unit in a RAM chip storing one unit of information and returning it in response to a particular address signal.

Central Processing Unit The CPU of a computer is essentially the "brain" of a system. It serves to fetch and execute each instruction from memory. It also performs all of the arithmetic and logical functions of the system. It contains a control unit, an ALU, and other related facilities with registers, clocks, or drivers. In some systems it may be comprised of several chips. In the Commodore 64, the 6510 microprocessor serves as the CPU.

Chaining Executing programs larger than the main memory of a computer by sequentially loading and executing modules of the same program.

Channel Logical connection from a CPU to an I/O device. Channels may be multiplexed, have dedicated ports, or a dedicated channel processor, to optimize communications.

Channel Disk Drive There are sixteen channels available on the 1541 drive. They are buffers through which information is passed to and from the disk. Data is not transferred directly from the disk to the user, but instead from the disk to the channel. The user can then INPUT# or GET# information from the channel.

Channels 0 and 1 are reserved by DOS for LOAD and SAVE commands and are not available to the user for data. Channel 15 is the command channel used to send disk commands to the controller and obtain error messages from the disk drive. Channel 15 is also unavailable as a data channel.

Channel Selector A small switch in the back of the Commodore 64 allows you to switch between channels 3 and 4. In areas where one of those stations is extremely

strong you are likely to experience interference while using your computer, and you should switch to the other channel. You must also make the appropriate change on your television.

Character Base See Character Generator.

Character Generator A section of ROM occupying memory locations 53248 to 57343, containing the data that will actually create a character on the screen. Any character on the screen is comprised of small dots or pixels in particular patterns. Eight bytes of data are required to create any character on the screen. All characters and PET graphic symbols are kept in the character generator. The VIC II chip makes use of ROM imaging to gain access to the character generator, even though it may be accessing a bank of memory not containing 53248 through 57343.

Character ROM See Character Generator.

Character Set The collection of characters available for display or processing on a particular computer or peripheral.

Character String A one-dimensional array or sequence of characters, encoded as bytes. Character strings have a length field, or are terminated by the zero byte.

Characters, Programmable Usually the data required to form the image of a character on the screen is brought from the character generator, a list of values in ROM that defines each character. The Commodore 64 allows the user to provide an alternate set of values to redefine the structure of characters. In this manner, the user can create his own character set.

CHAREN The name of a control line that banks a 4K byte of ROM containing the character generator in and out of the microprocessor's memory. When CHAREN is low, the microprocessor sees the character generator at address \$D000 to \$DFFF. When it is high, a group of I/O registers appear in that location.

Chip A rectangular silicon die cut from a wafer. See entries by number for each commonly used chip.

Chip Select Most large scale integration chips normally have one (or more) chip selects. These activate the chip to examine the rest of its pins, for example, the address bus. This information will in turn specify a location/register within the chip. Multiple chip-selects can replace decoders external to the chip, but do require extra pins.

CHKIN The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It sets up a previously opened file as an input channel. If the file is any device other than the keyboard, the file must first be opened with the OPEN routine. The X register must be loaded with the number of the logical file before using this routine. See KERNAL.

CHKOUT The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFC9, CHKOUT will set up a previously OPENed file as an output channel. If the file is any device other than the keyboard, the file must first be opened using the OPEN routine. The X register must be loaded with the number of the logical file before using this routine. See KERNAL.

CHROUT The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFD2, CHROUT will move one byte of data from the accumulator to an already opened channel. The OPEN and CHKOUT routines are used prior to this command to set up the output channel. The accumulator must be loaded with the byte of data prior to jumping to this routine. If the OPEN and CHKOUT routines are not used the data is sent to the screen. See KERNAL.

CIA See Complex Interface Adapter.

CINT The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FF8A, CINT initializes the 6567 video controller and the KERNAL screen editor. See KERNAL.

CIOUT The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFA8, CIOUT moves one byte of data from the accumulator to the serial bus. The LISTEN and SECOND routines must be used prior to this to set up a listening device. The byte to be moved is loaded into the accumulator before this routine is used. See KERNAL.

CLALL The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFE7, CLALL closes all previously opened files and resets input/output channels. See KERNAL.

CLC CLear Carry flag. An Assembly language instruction for the 6510 microprocessor that clears the carry flag bit. None of the other flag bits are altered.

CLD CLear Decimal mode. An Assembly language instruction for the 6510 microprocessor that clears the decimal flag bit. This sets the binary mode for the ADC and SBC commands. None of the other flag bits are altered.

Clear Signal to place a device or a circuit in an initial (usually zero) state.

Clear Screen Commodore control key SHIFT <CLR/HOME> is used to clear the screen. This may also be accomplished in a BASIC program by using either PRINT statement PRINT "<CLR/HOME>" or PRINT CHR\$(147). Either statement will clear the screen of any text/graphic display (standard character mode) and place the cursor on the top left corner of the screen.

CLI CLear Interrupt disable bit. An Assembly language instruction for the 6510 microprocessor that sets the interrupt mask bit to 0. This enables the interrupt and does not alter any other flag bits.

Client Tickler, The* A database program that allows you to determine what is being done for whom in a rapid, organized fashion. Disk; printer required. Powerbyte.

CLK CLock.

Clock* Teaches primary graders to tell time with a review at the end of the lesson. Cassette. Micro-Ed.

CLOSE The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFC3, CLOSE closes a logical file following the completions of all input/output operations on that file. The logical file number is loaded into the accumulator prior to executing this subroutine. See KERNAL.

CLOSE BASIC statement. CLOSE statement is used to close data files, or channels that are used for communication with external devices, such as the disk drive or the printer. The CLOSE operation frees up any data channels no longer in use and stores any incomplete buffers to the storage device (disk drive or cassette). Any files written to the disk that are accidentally left open are unreadable by the Disk Operating System (DOS), and are scratched by the VALIDATE command. See Validate, DOS.

The format is:

CLOSE<lfn>

<lfn> is a logical file number.

Clowns* A wonderful visual display of tricks and antics performed by graphic circus clowns. Commodore.

CLR BASIC Statement. This statement clears all the variables, arrays, files, user-defined functions, and GOSUB addresses, while keeping the main program intact in RAM memory. It is used to make additional space available for new variables by clearing the ones that are no longer needed.

An example is:

```
10 FOR I=1 TO 10: A(I)=2*I:NEXT:CLR
```

CLRCHN The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the Kernal. It is used to handle input/output operations. By jumping to address \$FFCC, CLRCHN clears all open channels and restores the I/O devices to their default values of 0 and 3 for keyboard and screen.

CLR/HOME This key moves the cursor immediately to the upper left corner of the screen. If pressed in conjunction with the SHIFT key the cursor moves to the same place and the screen is cleared.

CLV CLear oVerflow flag bit. An Assembly language instruction for the 6510 microprocessor that sets the overflow flag bit to 0. None of the other flag bits are altered.

CMD BASIC. The CMD statement prepares the specified output device to receive the object of PRINT statements. All data that would normally go to the screen in a PRINT or LIST statement gets diverted to the previously opened device and referenced in the CMD statement. To redirect data back to the screen it is necessary to send a PRINT# command. The format is:

CMD<ref>,<string>

An example is:

```
10 OPEN<ref>,4 20 CMD<ref>,<string> 30 PRINT "dat"
```

<ref> is a number from 1-127, arbitrarily set by the user to reference the file opened.

<string> is optional and can be any string within quotes or CHR\$ code.

CMOS Complementary Metal Oxide Semiconductors. Technology characterized by extremely low power consumption. Widely used in portable applications and battery-assisted memory systems. CMOS devices may operate from 3v to 12v and have ideal noise immunity characteristics. See MOS.

CMP CoMPare memory and accumulator. An Assembly language instruction for the 6510 microprocessor that subtracts the contents of the argument, or the contents of the address in the argument, from the accumulator. The result is not stored nor does it change the accumulator or memory, but the result does affect the sign flag bit, the zero flag bit and the carry flag bit. The addressing mode of the argument can be immediate, zero page, zero page X, absolute, absolute X, absolute Y, (indirect X), or (indirect) Y.

CODEC COder-DECodeR. A chip providing the essential translation of analog to digital conversion.

Colon (;) CBM BASIC. Used to separate multiple BASIC statements on one line. The line number at left refers to all the statements on that line. The maximum number of statements on one line should not exceed 80 columns because all statements or fractions of statements that are deleted by the interpreter.

Color Accountant • Compatible Upward

Color Accountant* A personal management program that helps you maintain budgets, appointments, mailing lists, income reports, etc. Contains complete documentation. Disk or cassette; printer required. Programmer's Institute.

Color Adjustment All adjustments of color intensity and hue are performed on the color TV. With the Commodore 64 some color combinations result in very poor resolution. It is possible to change the background color by POKEing different numbers from 0 to 15 in address 53281. The character colors can be changed by changing the cursor color from the keyboard.

Color Code The Commodore 64 is capable of generating sixteen colors. The colors can be generated by POKEing the code for a color into the appropriate memory location. The colors and codes are as follows:

black	0	white	1	red	2
cyan	3	purple	4	green	5
blue	6	yellow	7	orange	8
brown	9	light red	10	gray1	11
gray2	12	light green	13	light blue	14
gray3	15				

Color Craft* A unique graphics animation tool which gives the user five screen sizes and 25-200 pages associated with each screen size (a larger screen will have fewer pages available). The command line at the top of the page helps the user through the modes of the program (Form, Edit, Copy, Save, Run, and Load). Once the screen size is selected using the Form command, the user can enter the Edit mode and create any combination of text and block-graphic images on the screen. Cursor colors may be selected to add color to the characters and six directions are available for cursor movement. Each page holds a picture and the program's built-in timer allows the user to display these pages in sequence. By varying the display time of each page, special animation effects can be created on the screen. Disk SAVE and LOAD commands are available to store and retrieve these files respectively. COPY command copies a picture from one page to another. The program comes with an easy to follow documentation that includes a Glossary at the end for quick reference. Sim Computer Products, Inc.

Color Keys The color of the cursor and subsequent characters printed on the screen can be altered from the keyboard. The colors can be implemented using the CTRL key and the color keys along the top row simultaneously. A second set of colors can be implemented using the special Commodore key in the bottom left part of the keyboard with the color keys along the top row.

Color Memory or Color RAM A section of RAM from address 55296 to 56295. In the standard character mode these addresses contain the color value of the characters displayed on the screen. POKEing different values at these addresses will change the color of the characters displayed. In the multicolor character mode, four values can be placed in each address to give four possible colors for each character.

Column Addition* Helps third through eighth graders with math skills, especially dealing with columns of numbers. Cassette. Comm*Data Computer House.

Combinational Logic A circuit with Boolean logic functions and no memory.

Comma (,) CBM BASIC. A delimiter used to separate the input and output of variables and constants.

Command A statement which causes the computer to carry out a specific action. Commands differ from instructions in several ways. A command is usually a complete specification of an action, while instructions are usually combined in dozens or hundreds to make a useful program. Commands are usually acted upon immediately by the computer, while instructions are saved for later execution in a program. Commands are acted on by the basic operating system of the computer, while instructions must be processed by a particular program such as the BASIC interpreter.

Command Channel See Channel Disk Drive.

Command Processor A program which accepts a command (usually from a keyboard), and causes it to be carried out. Some command processors, including the Commodore 64's, contain the programming required for all commands they process. Others do not carry out any commands directly. Instead, these examine the command, determine what other program (if any) can carry it out, locate the program, and start it running. Still another type of command processor carries out some commands directly (internal commands), but locates and runs other programs for some commands (external commands).

Comment Field A field within an instruction, for explanations or remarks, that is ignored by the interpreter.

Comments BASIC. See REM.

Commodore Pilot 64* With this package you can run Common Pilot programs on the Commodore 64 without any modification, as well as enhanced Commodore 64 programs. You can define your own characters and sprites and create sounds and music. Commodore.

Commodore 64 DOS Wedge* This program gives you some short cuts in loading, saving, and using directory commands in BASIC. Permits easy use of disk storage. Commodore.

Compact* A complete terminal control package that allows you to record, read to and from disk, convert files, and print incoming data. Microtech.

Compatible, Upward (Versions of Programs) The term upward compatible indicates that programs developed for one version of a programming language, operating system, application software package, or computer will work without alterations on an expanded, more powerful version of the same language, system, or package.

In hardware, upward compatibility refers to the possible building up to more powerful models without reprogramming.

Compile Time The point in the processing of a program when it is being translated from source code to object code by a translator (compiler or assembler).

Compiler A translation program which converts high-level instructions into binary instructions for direct processor execution. Any high-level language, such as BASIC or COBOL, requires a compiler or an interpreter.

An interpreter translates each statement of the program each time the statement is executed, whereas a compiler translates the complete program once, producing object code that can be executed repeatedly. Any change in the program requires recompilation. The code produced by compilers may be longer and/or slower than the code generated by Assembly language source code.

Complementing The action of changing each 1 to a 0, and each 0 to a 1.

Complex Interface Adapter The Commodore 64 contains two Complex Interface Adapter (CIA) chips that serve as mediating devices between the microprocessor and peripheral devices. All data from the disk drives, users port, or the keyboard first moves into registers within the CIA chips. When the CIA chips receive a signal from a peripheral device indicating that data is ready, (through interrupt sequences), the CIA sends its own interrupt Machine Code (IRQ or NMI) to the microprocessor. The 6510 microprocessor finishes executing whatever instruction it is working on and then looks to the CIA chips to see where the interrupt is coming from. Once the microprocessor receives that information it jumps to the operating system to see what to do next. The operating system will tell the microprocessor where to get the in-coming data and where to put it. The CIA maintains several registers that can be addressed directly by the user to set up input/output ports and handshaking operations.

Condensed A print function available on some dot matrix printers. When the appropriate control code sequence is sent to the printer, the size of subsequent characters to be printed is reduced to seventeen characters per inch from ten characters per inch in the standard mode. In the Gemini, this function is accessed by sending ASCII code sequence CHR\$(27) CHR\$(66) CHR\$(3). On an Epson printer, use ASCII code 143 to turn it on and 146 to turn it off.

It emulates the Vic printer, and allows the user to print the complete set of Pet graphic characters available on the Commodore 64. It supports the standard printer formatting features and serious applications such as word processing, database management, spreadsheets, and graphics. Many versions of the Connection download data files from the computer and give the controls back to the user for further processing, while simultaneously feeding the data to the printer. Micro-Ware Distributing, Inc.

If the program interrupt occurred due to

Contractions • CP/M Commands

an error, the error message "CAN'T CONTINUE" will result when the CONT command is used to re-start the program, or when an attempt is made to change the program.

CP/M Control Program for Microcomputers.

CP/M—Cold Start A cold start is performed when the system is first turned on. The start-up operation, sometimes referred to as bootstrap, involves an automatic loading of the CCP, the BIOS and the BDOS from the system disk into the main memory. The control at this point is transferred to the BIOS.

CP/M—Commands The following is a table of CP/M commands, each followed by its format and a brief description.

COMMAND	FORMAT (<i><argument></i>)	DESCRIPTION

CP/M—Operating System A popular single-user operating system for 8080, Z80, and 8085-based microcomputers, created by Digital Research. It is a collection of programs available on the system disk which, once loaded into the system using either a bootstrap loader or the resident monitor, will take over the system operation, communications with peripheral devices (such as the drives or the printer), and all management of computer memory space as well as disk files. The main advantage of using this operating system instead of the computer's operating system lies in the universal nature of CP/M (it can run on any microcomputer and has an extensive software support from third party vendors). It also operates with considerable speed and efficiency as compared to an operating system that is built around a higher-level language such as the Commodore's BASIC on the Commodore 64. BASIC offers simplicity and ease of handling to the beginning user. However, for most serious applications, it tends to be too slow and takes up too much memory. CP/M on the other hand fully uses the computer's resources and is more versatile, using less memory. It can be executed on the 6502 based systems (such as the Commodore 64) with the aid of a plug-in cartridge and a system disk (to be available soon from Commodore.)

CP/M—Organization CP/M is organized in computer memory in the form of logical components or software modules. The three functional modules are called BIOS (BASIC Input/Output System), BDOS (BASIC Disk Operating System), and the CCP (Console Command Processor). See BDOS, BIOS, CCP.

CP/M—Warm Start A warm start is performed to interrupt the system and start over again. It is also performed when a disk is replaced with another in a drive that was previously read by BDOS, and the new disk directory needs to be logged in place of the old. Warm start differs from cold start only in that the BIOS memory image remains unaltered during a Warm start. A control C is used to warm start the CP/M. See also CP/M Cold Start.

CP/M—Control Characters Following is a table of the control character commands and their functions.

KEY	FUNCTION	REMARKS
Control-C	Warm Start	Performed to abort program execution or replace disk in a drive.
Control-H	Delete Character	Cursor backup to previous character.

CPS Characters Per Second or Cycles Per Second.

CPU See Central Processing Unit.

CPX ComPare to X register. An Assembly language instruction for the 6510 microprocessor that subtracts the argument or the contents of the address in the argument, from the contents of the X register. It does not store the result, nor does it alter the contents of the X register or the accumulator; but it does affect the sign flag bit, the zero flag bit, and the carry flag bit. The addressing mode of the argument can be immediate, zero page, or absolute.

CPY ComPare to Y register. An Assembly language instruction for the 6510 microprocessor that subtracts the argument, or the contents of the address in the argument, from the contents in the Y register. It does not store the result, nor does it alter the contents of the Y register or the accumulator; but it does affect the sign flag bit, the zero flag bit, and the carry flag bit. The addressing mode of the argument can be immediate, zero page, or absolute.

Craps* A computer version of the popular dice game. Cassette. RAK Electronics.

Crash A situation where the system becomes inoperative due to a hardware or software malfunction. A head crash refers to the accidental impact of the read/write head upon the disk surface.

CRC Cyclic Redundancy Check. A binary polynomial used to check information in blocks of data. All single-bit errors are detected. When used with an additional Longitudinal Redundancy Check (LRC), all two-bit errors are detected and all one-bit errors are corrected. The two check sums (CRC and LRC) are calculated based on the data and appended to it. When the data is received or reread, the CRC and LRC are recalculated and compared to the earlier CRC and LRC. Any difference indicates that a bit has changed. The CRC and LRC act like parity bits, except that they work on a whole block of data rather than one byte.

Cribbage* A computerized version of this classic card game. Disk or cassette. Abacus Software.

Crosstalk Two signals interfering with one another.

CRT Cathode Ray Tube. A computer terminal using a CRT that displays characters or pictures. Also called a monitor, screen, terminal, etc.

CRTC CRT Controller. A chip or circuit which provides necessary control signals to interface a CRT to the input/output bus of an MPU.

The same two keys can be used with the shift key to move the cursor up and to the left. If the cursor keys are held down the cursor will scroll across the screen.

The CLR/HOME key will return the cursor to the upper left corner of the screen.

The INST/DEL key can be used to move the cursor to the left and to delete any character the cursor encounters. Pressing the INST/DEL key in conjunction with the shift key will leave the cursor in the same position, but will move all the text on the right side of the cursor to the right.

The space bar at the bottom of the keyboard will move the cursor to the right and erase any character it encounters.

The RESTORE key, pressed in conjunction with the RUN/STOP key, will clear the screen and move the cursor to the upper left corner or to the home position.

The RETURN key will return the cursor to the left side of the screen and move it down one line.

If you try to move the cursor down off the screen, it will remain on the last line and all text entered previously will move up one line.

The cursor can also be moved with basic programming using the PRINT command followed by the appropriate CHR\$ code. For example:

```
PRINT CHR$(17)
```

followed by a carriage return, will first move the cursor to the left and down one line (as a result of the RETURN) and then move the cursor down one line (as a result of CHR\$(17)). The CHR\$ codes affecting the cursor are listed below.

RETURN CHR\$(13)
Clear HOME CHR\$(19)
CURSOR right CHR\$(29)
CURSOR up CHR\$(145)
CURSOR down CHR\$(17)
INST/DEL CHR\$(20)
SPACE CHR\$(32)
CURSOR left CHR\$(157)

<constant> may be a numeric or string constant. String constants in DATA statements do not need to be surrounded by quotation marks, unless the string contains commas, colons, or significant leading or trailing blanks.

DATA statements are nonexecutable. They can be placed

anywhere in a program. A DATA statement may contain as many constants as will fit on a line, and any number of DATA statements may be used in a program. The READ statements access the DATA statements in line number order. The information that is in a group of DATA statements can be thought of as one continuous list of items, regardless of the number of items on one line.

If the variable type is defined in the READ statement as numeric, the corresponding constant in the DATA statement must be numeric as well. If the variable type is defined as string in the READ statement, the corresponding constant in the DATA statement must be string. For examples see READ.

DATA statements can be “reread” through the use of the RESTORE statement. See RESTORE.

Data Acquisition The collection of data from external sensors, usually in analog form.

Data Bus The set of lines which carry data. All system components are normally connected to the data bus. When data is ready to be moved into the accumulator the address bus is set to the specific address from which the data will come. The location is connected to the data bus. It is the only location connected to the data bus at that time. The byte of information thus moves from the accumulator through the data bus to the addressed memory location. The first address may then be disconnected and a second address where the data in the accumulator is to be moved is set onto the address bus. This connects the second location. In this manner information is moved under the control of the microprocessor to and from the different devices and peripherals. See DMA.

Data Communications Multiplexer A device which allows several communications processes (or “conversations”) to operate concurrently over a single channel (such as one phone line). This can work through 1) time-division multiplexing, which oscillates the channel rapidly from one conversation to another; 2) frequency-division multiplexing, which uses shifts around two different frequencies to simultaneously transmit two different conversations; and 3) other, more complex methods.

Data File A named collection of information usually stored on magnetic media.

Data Separator A circuit in disk controllers which separates the data from the carrier in the signals read from the disk surface.

Data Set File or a group of related data elements.

Data Tablet A graphic input peripheral which digitizes the position of a stylus on a special sensory surface.

Data Transfer Rate The rate at which data is transferred from one place to another, such as from disk to memory or from memory to memory.

Data Types A specific interpretation applied to binary data, such as integer, floating point, or string.

Database A program that facilitates information storage and retrieval. Generally, databases are designed to accept data from the user in a user-defined format. Data storage is accomplished by creating files on disks, and the information to be stored is packaged in the form of records. All records in a file have the same format. Retrieval of the information involves selecting and sorting the type of information desired, and processing the selected records for display or printing. Most databases available for the Commodore 64 are general purpose packages that can be used for anything from mailing lists to recipes. Depending upon the sophistication of the particular database, a user can perform sorts and searches at many levels. Many operations may be performed on the selected records, including statistical summaries and routine arithmetic operations. These records may be printed in a user-defined format or saved in another file for further processing. For a review of a specific database for the Commodore 64, refer to its product name.

Database Management Software See Database Manager; Datalog Database; Date Due; Easy Mail; Filing Assistant, The; Infomast; M'File; Powerfile; and Research Assistant 2.0.

Database Manager* A database management system that comes with a well-documented user's manual and a tutorial on each of its functions. The program is written in Machine language for speed and efficiency, is menu driven, and makes full use of the cursor keys, thereby making it easy for the user to enter/edit records. Other features are free-form design and input, sort on any field or level, and calculated fields. The maximum number of records per file is 65,535. Maximum record size is 2,000 characters, maximum fields per record 200 characters, and maximum field size 250 characters. These features make the database very versatile for use as an information management system. The program uses four different file structures in its operation. They are 1) Data dictionary file—a sequential file that contains information such as record size of the database file, form of the record displayed on the screen and the position of each field in the record; 2) Number of records file—a sequential file that keeps track of the number of records in a file; 3) Database file—a relative file containing the information for each database record; and 4) Sorted index file—a sequential file that contains the beginning record number and the character representation of the sorted field. Merge capability is also available with some of the most popular word processors to create personalized form letters. Mirage Concepts, Inc.

Datalog Database* A general-purpose database management system. The package comes with easy to follow documentation and sample data files to help you learn to use the system. The program uses relative files to store and retrieve data elements. It is capable of maintaining up to 1000 records per disk with up to twelve fields per record. Record format is user-defined and search option is available for every field in the record. Records may also be displayed on the screen or dumped on the printer in user-defined format. Other special features are the facility for

Typical debounce time is five to ten milliseconds for stable contact. Debouncing may be performed by hardware (latch) or software (delay).

Debug or Test a Program A programmer must insure that a program will correctly process all of the types of data for which it is intended. Samples of the data are prepared (test data), and the program is executed using this data (a test run). The program's outputs (reports, screen displays, files, etc.) are then verified to be as specified. An error in the

processing logic of a program is called a “bug,” hence the terms “debug” and “bug-free.” BASIC includes debugging aids for BASIC programs.

DEF FN BASIC Statement. Defines and names a numeric expression or equation. The format is:

DEF FN<name> <variable> = <expression>

<name> is a valid variable name. This name, preceded by FN, will be the name of the function.

<variable> represents a variable name in the function definition that will be replaced with a value when the function is called.

<expression> defines the return value of the function. It can be numeric or string, but must match the type that was declared by the <name>.

The function type determines whether the function returns a numeric or string value. The type of function is declared by <name>, in the same way as variables are declared. If the type of <expression> does not match the function type, a “Type mismatch” error is displayed. If the function is numeric, the value of the expression is converted to the precision specified by <name> before it is returned to the calling statement.

A DEF FN statement must be executed to define a function before you may call that function. If a function is called before it has been defined, a “Undef’d Function” error message is displayed. On the other hand, a function may be defined more than once. The most recently executed definition is used.

Default See Default Value.

Default Disk Drive or Current Disk Drive* CP/M keeps an internal record of which disk drive is currently considered the “default disk” or “default drive.” When you start a CP/M or BASIC session, the default disk drive is always A. To change the default disk drive to B, enter B: or to go back to A as default, enter A: to determine which is the default disk drive, look at the prompt (A> or B>) from CP/M.

Default Parameters The parameter values supplied by a computer system or a program when no explicit values are provided by a program or a programmer.

Default Value Or, Default. A value for a parameter or variable which will be supplied by a program or system, if you do not specify a value.

Delay Loop Used to Freeze or Hold Screen Display. To freeze the screen briefly while the operator using your program reads a message, just write a delay loop after you print the message:

```
1000 FOR Y = 1 TO 2000:1010 NEXT Y
```

To freeze the screen until the operator is done with it, put in a dummy input statement and instruct the operator to press ENTER to proceed. The input variable need not be used in your program:

```
1000 INPUT "Press ENTER to continue";A$
```

Such a system typically includes a microcomputer, monitor, printer, mass-storage (often disks or hard disk), PROM programmer, and an in-circuit emulator. Development Tools Hardware and software aids for developing programs and/or hardware systems.

Device Names Names which may be used in place of a file name in many DOS or BASIC commands to specify that data is to come from or go to a device (keyboard, CRT, printer, etc.), rather than a disk or cassette file.

Device Not Present A message indicating the device specified in a OPEN, CLOSE, CMD, PRINT#, INPUT# or GET# statement was not available. Often it indicates that you forgot to turn on your printer or disk drive. Occasionally, poor cable connection or a faulty circuit in a peripheral will cause this message.

Device Number A device number is a number written into the RAM of the disk drive which is used to select a particular disk drive from other peripherals or drives. It is referenced in load and save commands (usually 8 unless changed by user). The number is written into RAM each time the drive is powered up, and comes from a hardwired jumper in the drive. The number in RAM can be changed using the following command:

```
OPEN15,8,15
PRINT#15,"M-W:"CHR$(119)CHR$(0)CHR$(2)CHR$(n+32)
CHR$(n+64)
```

n is the drive's new number assigned by the user.

DIM BASIC Statement. Any subscripted variable (e.g., A(1)) assigned by a user is automatically given a location by the Commodore 64. When a program is running, if it encounters a variable it goes to the assigned location to find its value. The Commodore 64 can only accommodate 10 subscripted variables without first setting up special locations for the variables. The DIM statement is used to set up this space. The format is:

`DIM <var><sub>[,<var>(<sub>)]`

<var> can be any normal variable with only the first two characters seen by the computer. They can be integers, string, or floating point, with the appropriate variable signs (\$,%).

<sub> is the subscript. It can be any number from 0 to 255 as long as there is enough memory in RAM to accommodate it.

`DIR<filename or filetype>`

See also CP/M Commands.

Direct Addressing (Short Addressing) An addressing technique which allows short instructions with the address field limited to eight rather than sixteen bits. Used in Assembly language programming.

Directory Disk drive. A list of all programs and files on a disk. Each directory entry on the 1541 contains the name of the file assigned by the user, the type of file, a list of blocks used, and the starting block location for the file. The format for obtaining a list of files in the directory is:

```
LOAD"$",8
READY
LIST
```

DIRECTORY ERROR An error message from 1541 disk drive generated when there is a problem with the Block Availability Map. The Block Availability Map (BAM) keeps track of the blocks used on the disk where it is stored. It is

also kept in disk memory when the drive is on. If the BAM becomes corrupted on disk memory this error may be generated. It is necessary to use the INITIALIZE command to correct the situation.

Disk A flat, circular, magnetic storage medium which is rotated while in use.

Disk A mass-storage device using a flexible (floppy) mylar disk to record information. The disk is sealed in a square plastic jacket lined with a soft material which cleans the disk as it rotates. A cut-out slot provides access for the moving head which must actually come in contact with the disk surface in order to read or write. Other holes in the jacket provide access to sector index holes in the disk. Disks are hard-sectored if the sector start points are marked by holes in the disk. Soft-sectored disks have only one (or a few) holes to mark the start of the track. The sector start marks are placed on the soft-sectored disk under software control in a process known as formatting the disk.

Disk—Commodore 8050* A Commodore disk drive unit capable of interfacing through an IEEE interface with the Commodore 64. It actually houses two separate drives, each formatting a 5-1/4" floppy disk for 509K bytes of storage. This results in a total of nearly 1 megabyte of storage. It contains its own controller with 16K ROM for Disk Operating System and 4K ROM for a buffer. It is capable of copying from one disk to the other.

Disk—1541 Disk Drive* The upgraded 1540 disk drive manufactured by Commodore. It is directly compatible with the Commodore 64 and connects with the 6-pin DIN socket in back of the Commodore 64. It is compatible with the VIC 20 after sending the USER Command UI. See UI, User Command

The 1541 accepts standard 5-1/4 inch single sided, single density disks. It has a capacity of storing up to 170K bytes of information and up to 144 different programs and/or files on a single disk. The drive contains its own controller and includes 16K of ROM and 2K of RAM memory. Two ports in the back of the drive enable you to daisy chain up to five drives and one printer.

Following the NEW command the drive formats the disk into thirty-five tracks, 683 blocks, with seventeen to twenty-one sectors per track (depending on distance from center) and 256 bytes per sector.

Information is accessed one bit at a time and transmitted serially to and from the computer, which greatly reduces its relative speed. Its internal ROM and RAM are efficient since some commands can be executing while the computer continues to work.

The disk drive has green and red LEDs in front with the green indicating that power is on. When the red LED is on, data is being exchanged, and the disk should not be removed. If the red LED is flashing, there is an error.

The 1541 stores four types of files: program files, sequential files, random files, and relative files. See each for specific information.

Disk ID Mismatch An error message from the 1541 that occurs when the drive tries to access a disk that had not been formatted. It can also occur if the disk is defective.

Display Sending graphic and/or alphanumeric information to a device such as a CRT or a seven-segment LED.

Division by Zero Division by zero is not mathematically possible and causes this error message on the Commodore 64. Be careful with variables that might end up with zero after some computation; if you divide by that variable you will get this message.

On the Gemini-10X, when the appropriate control code sequence is transmitted to the printer, the characters are printed once, then the paper is moved up 1/144 inch and the characters are reprinted. It is analogous to bold-face printing.

Format of the ASCII code sequence for the Gemini 10X:

CHR\$(27) CHR\$(71) turns "on" double strike. CHR\$(27) CHR\$(72) turns "off" double strike.

(This function can be used on the Gemini with any other print-style command.)

Dynamic Circuitry which stores information as charges on MOS capacitors; usually volatile and requiring periodic refreshing.

Dynamic Memory MOS RAM memory using dynamic circuits. Every bit is stored as a charge on a single MOS transistor. This allows very high density (only one transistor is used per bit). Since the stored charge leaks, a typical dynamic memory must be refreshed every 2 milliseconds by rewriting its entire contents. This does not slow down the system, but does require additional memory-refresh logic. Dynamic memory chips are cheaper than static ones, and are generally preferred for memory sizes over 16K. Dynamic memory is also volatile—the data stored is lost when power is turned off or interrupted.

Dynamic Memory Allocation Varying allocation of memory to multiple concurrent programs according to their needs, and a strategy for optimizing performance.

E-Beams Electron Beams.

Echo A character received from the keyboard is sent to the printer or screen for display.

Echo Hardware Testing. A loop-back or "Echo" technique is used to test the circuits of an input/output device by "looping" whatever is output back into the computer, as if it were input. In this way the circuits inside the computer are tested in isolation from the circuits in the external device to help isolate where a fault lies.

"Echo-keyboard to screen Echo" describes the process of sending characters keyed on the keyboard to the screen for a visual confirmation of what has been typed. There are no hardwired connections between the keyboard and the screen. The keyboard simply enters characters into memory.

ECL Emitter Coupled Logic. Bipolar Transistor—Transistor Logic (TTL) device using variations in the current, rather than voltage levels, to control bit and gate switching. ECL writes as much as ten times faster than other TTL or MOS circuits. ECL-TTL circuits consume a lot more power and produce a lot more heat.

ECM Electronic Counter Measures. Using electronic devices to jam or evade an opponent's electronic equipment. Used in military and espionage situations.

Edge Card Connector An edge of a printed circuit board which has DOS or BASIC commands to specify that data is to come from or go to a device (keyboard, CRT, printer, etc.), rather than a disk or cassette file.

Edge Card Connector An edge of a printed circuit board which has exposed conductors ("ways") to form an electrical connection with another board through a slot.

Editor Screen Editor. The Commodore 64 comes with a screen editor that enables the user to enter BASIC lines and to modify and view those lines from the screen.

The screen editor can distinguish between direct mode (which does not have a line number before the entry) and program mode (which has a line number before each BASIC line). Characters entered from the keyboard can be appended by moving the cursor to the incorrect character and entering the correct one. Characters can be deleted to the left of the cursor by pressing the INST/DEL key. Characters can be deleted to the right of the cursor by pressing the space bar. An extra space can be created between words by moving the cursor between words and pressing the SHIFT key in conjunction with the INST/DEL key.

In program mode each line of BASIC is stored in memory. That line can be changed simply by listing the program line, making the appropriate changes, and then pressing the return key (the changes are not made until the return key is pressed). A line can be deleted by entering the line number without any data following it and pressing return. No listing will have the deleted line number.

EDP Electronic Data Processing. Processing data with electronic machines such as adding machines, calculators, and computers.

Created at MIT in 1966, Eliza is designed to run on a large mainframe. Emphasize A print function available on some dot matrix printers. When the appropriate control code sequence is sent to the printer, it prints each character twice, moving the position of the print head slightly the second time so that the character printed appears to be in boldface. This function is accessed in the Gemini 10x printer by sending ASCII code sequence CHR\$(27) CHR\$(69). To turn this mode off, use control codes CHR\$(27) CHR\$(70). In the Epson printer, use ASCII code 155, 197 to turn the emphasized mode on and 155, 198 to turn it off.

Emulation Simulation in real time. One computer emulates another by executing an emulator program that makes it interpret the same instruction. See Pet Emulator.

END Statement marking the end of a program in several programming languages.

END BASIC Statement. Used to terminate program execution, close all files, and return to command level. The format is:

END

END statements may be used anywhere in a program where you wish to terminate execution. END differs from STOP in that it does not cause a "Break" message to be printed, and it closes all files. An END statement at the end of a program is not imperative.

END has a different function with the BASIC Compiler. See your Compiler Manual for more information.

The addressing mode of the argument can be immediate, zero page, zero page X, absolute, absolute S, absolute Y, (indirect) S, and (indirect) Y. The result of the Exclusive-OR function is then placed in the accumulator and can alter the sign flag bit and the zero flag bit.

ERA<filename or filetype>

See also CP/M Commands.

Erase All BASIC Program Lines To start a new program type:

NEW

This completely erases all lines now in BASIC's memory, so if it's something you want to keep and haven't already saved on disk, SAVE it first. If you don't erase the program in memory before starting on another, you will usually wind up with an unusable combination of mixed lines from *your old* and new programs.

Erase BASIC Program Lines (DELETE) To delete a BASIC program line enter the line number and press Return.

Erase Disk File • Error Messages

Erase Disk File See Scratch.

Erase Screen To clear the screen, press <shift> <CLR/HOME>. When in a program, press <RUN/STOP> <RESTORE> to halt execution and clear screen.

Error Channel See Channel Disk Drive.

Error Correcting Code A data storage or transmission code using extra bits which will automatically detect and correct single or multiple-bit errors.

Error Correction Methods used to correct erroneous data produced by defective or unreliable data storage and transmission systems.

Error Message A statement or code printed out or displayed on the screen by the operating system or a program to let you know what is happening. Error messages tell you something about what went wrong.

Error Messages The Commodore 64 and 1541 disk drive produce a number of error messages. The following is a list of those messages with an explanation of the problem.

BAD DATA indicates that while a program was set up for receiving numeric data, it received string data instead. **INPUT#5,A** indicates that the data being input from the open file referenced by five must be a numeric value. If an alphabetic character or word is input, the **BAD DATA** message will appear.

BAD SUBSCRIPT indicates that the program encountered an element of an array that was outside the range dimensioned in the program. If you neglect to dimensionize an array, and you attempt to use more than ten elements per variable you will receive this error message. For example:

```
FOR X = 1 TO 20:A <X> = X:NEXT
```

BAD SUBSCRIPT will appear if you do not first dimensionalize A<X>.

CAN'T CONTINUE indicates that you can not use the **CONT** command at this time. If you have not run the program yet, and you inadvertently enter **CONT**, this message will appear. The **CONT** command cannot be used after an error has caused program execution termination or after you have edited program lines.

DEVICE NOT PRESENT appears when the device specified in an **OPEN**, **CLOSE**, **CMD**, **PRINT#**, **INPUT#**, or **GET#** statement was not available. Often it indicates that you forgot to turn on your printer or disk drive. Occasionally a poor cable connection or faulty circuit in a peripheral will cause this message.

DIVISION BY ZERO is not mathematically possible. Be careful with variables that might end up with zero after some computation. If you divide by that variable you will get this message.

EXTRA IGNORED appears if the **INPUT** statement is expecting only one variable (**INPUT A**), and the user enters two. The second is ignored.

FILE NOT FOUND appears if you attempt to load a file, by

name, from disk or cassette and the file can't be found. Be careful when specifying the file name. A name with a capital letter is different from one with a lower case letter, and an extra space between words will change the name. Be precise.

FILE NOT OPEN indicates that the user has tried to use the commands **CLOSE**, **CMD**, **PRINT#**, **INPUT#** or **GET#** with a file that was not already properly opened.

FILE OPEN indicates that the user attempted to open a file using a number that had already been used to open a file. Remember to keep file numbers, device numbers, and channel numbers unique.

FORMULA TOO COMPLEX indicates that the expression encountered has too many characters for the computer to deal with. It can also indicate that too many parentheses are being used in a formula.

ILLEGAL DIRECT indicates that the user attempted to use the **INPUT** statement in the direct mode. **INPUT** can only be used in program mode (with a line number).

ILLEGAL QUANTITY appears if the number used as the argument of a statement is out of the Commodore 64's allowable range. Be careful with variables in a program, during computation they may exceed limits.

LOAD appears when there is a program with a program on tape.

NEXT WITHOUT FOR appears when a variable with the **NEXT** statement doesn't correspond to the variable in the **FOR** statement.

NOT INPUT FILE indicates that a program is trying to **INPUT** or **GET** data from a file that was specifically opened as an output file.

OUT OF DATA indicates that a program is attempting to **READ** from a **DATA** statement and there is not a one to one correspondence between the number of **READs** and the amount of data.

OUT OF MEMORY indicates that there is no more **RAM** memory available. It also occurs when too many **FOR** loops are used, or when there are too many **GOSUBs** used. Remember arrays, though they may only take one line to dimensionalize, often occupy vast areas in **RAM**.

OVERFLOW indicates that a value computed has exceeded the maximum value allowable on the C 64, 1.70141884E+38.

REDIM'D ARRAY indicates that an attempt was made to use the same variable to dimension two arrays. If a variable is used in a program before it is dimensioned, the computer automatically gives it a dimension of ten. If the program then attempts to dimension the array, the error message will appear. It is best to use the **DIM** statements in the beginning of a program.

REDO FROM START is encountered when the user enters string data into an **INPUT** when the computer was expecting numeric data. If, in a program, the statement reads **INPUT A**, the program will prompt for input. If the user enters a word at this point, the error message will appear (**A** is a floating point variable). The user can reenter the correct input and the C 64 will continue.

RETURN WITHOUT GOSUB is encountered when a program reads a RETURN statement and has no GOSUB to which to return.

STRING TOO LONG appears when a string greater than 255 characters is read. Be sure that when you are inputting multiple variables that you include delimiters (commas, semicolons, returns) between variables.

SYNTAX ERROR appears when the computer reads a line and does not recognize the BASIC command. Even the slightest variation from the format listed in the Users Guide or Reference Guide will result in a syntax error. Be sure to include commas and parenthesis where shown.

TYPE MISMATCH appears when a variable designated as either numeric or string is equated with the wrong type. If you attempt to equate A = "G" you are trying to make a floating point variable equal to a character. Be sure and use quotation marks around string data.

UNDEF'D FUNCTION appears when an FN statement is used without first having a DEF FN statement.

UNDEF'D STATEMENT is encountered when the computer is programmed to read a line number that does not exist. If you have a GOSUB statement to a line number that does not exist this message will occur.

VERIFY is encountered when the VERIFY command was used to compare the data in the memory with the data on a tape or disk, and an inconsistency was found. Attempt to load or save the program again.

READ ERROR is encountered when the 1541 drive is unable to correctly read data on the disk. The 1541 drive is capable of being more specific by reading the error channel (#15) and decoding the error number. The following numbers correspond to the particular error.

20: The disk drive is unable to find the header of a block due to an illegal sector number or corrupted data.

21: The disk drive finds the beginning of a sector by reading a synchronization mark at the beginning. This message appears if the drive can't find that sync mark. It can result from not having formatted the disk (using NEW command) or if the disk is absent or not seated properly. Hardware failures can also give this message.

22: If the disk drive has been given a BLOCK command using random files and the block can not be found, this number appears on the error channel. The user may have tried to read or verify a track or sector number that does not exist.

23: The disk drive has a method of verifying data as it is read from the disk using a checksum. This message indicates corrupted data or a hardware problem.

24: If a byte read from disk reveals an invalid bit pattern this error will develop. It can be from a hardware problem.

27: The disk drive has a method of verifying the header information as it is read from disk using a checksum. If there is an error in the header, this message may appear. It can also result from hardware failure.

WRITE ERROR results if there is an inconsistency between the data that is written onto disk and the data that should be

written onto disk. Two specific write errors are shown below:

25: If the data written on disk does not equate with the data in Disk RAM from where it was just written, this error appears.

28: At the beginning of sector a synchronization mark is written. When writing to disk the drive attempts to read these sync marks. If one does not appear, this error is incurred. It happens with a bad disk, unformatted disk, or a hardware problem.

WRITE PROTECTION ON is the result of attempting to write to a disk that is write-protected. Either there is an adhesive tab over the write-protect notch, or there is no write-protect notch on the disk.

DISK ID MISMATCH is incurred when the 1541 drive attempts to access a disk that has not been formatted. It can also result from a bad disk.

SYNTAX ERROR indicates that the 1541 drive could not understand one of the commands sent to it. Specific syntax errors can be determined by reading the error number off the error channel (#15). They are as follows:

31: The drive does not understand the command sent. Make sure the command is in the correct format.

32: The command sent has exceeded the 58 characters allowable in a command.

33: The user has attempted to use pattern matching incorrectly in the LOAD or SAVE commands.

34: A file name is missing from a command, or a colon is absent.

39: The disk does not recognize a command sent through the command channel (#15).

RECORD NOT PRESENT is displayed by the 1541 drive when the user attempts to INPUT# or GET# data beyond the last record in a file. It can also occur if the user attempts to use the position commands beyond the last record of a relative file.

OVERFLOW IN RECORD PRINT# is displayed by the 1541 drive when more than the defined or allowable number of characters if PRINT#ed to the drive. Remember the carriage return is included in the characters sent.

FILE TOO LARGE is displayed by the 1541 drive to indicate that a disk overflow will occur.

WRITE FILE OPEN is displayed by the 1541 when an attempt is made to open a write file that has not been closed.

FILE NOT OPEN is generated by the 1541 drive when a file is accessed and has not been opened.

FILE NOT FOUND is generated by the 1541 drive when a user attempts to access a file that does not exist on a particular drive or disk. Be sure that the file being accessed is spelled correctly and in the exact format as that on the directory.

FILE EXISTS is sent by the 1541 disk drive when the user attempts to open a file by a name that already exists.

FILE TYPE MISMATCH is sent by the 1541 disk drive

Error Messages • Expansion Port

when the user attempts to open a file by name and type that is stored as a different type.

NO BLOCK is sent by the 1541 disk drive when a user attempts to use the **BLOCK-ALLOCATE** command to allocate a block that is already in use. The error channel #15 returns this message as well as the track and sector of the next available block.

ILLEGAL TRACK AND SECTOR is sent by the 1541 disk drive when the user tries to access a track or sector that is not available or does not exist.

ILLEGAL SYSTEM T OR S is sent by the 1541 disk drive when the user tries to access an illegal track or sector.

NO CHANNEL is generated by the 1541 disk drive when a user tries to open more than the allowed number of channels. Up to five sequential files or six direct access channels may be opened simultaneously.

DIRECTORY CHANNEL is sent by the 1541 drive when there is a problem with the Block Availability Map. The BAM keeps track of the blocks used on the disk and is kept on the disk. It is also kept in disk memory when the drive is on. If the BAM becomes corrupted on disk memory the error above may be generated. It is necessary to use the **INITIALIZE** command to correct the situation.

DISK FULL is sent by the 1541 drive if the user attempts to add to a disk that does not have enough room for the entry, or if the user attempts to create more than 144 files.

ESC **ESCAPE**. A character that causes the terminal and/or processor to interpret subsequent characters differently. Escape codes are used to indicate a sequence of control messages in ASCII.

ESF-20/64 Stringy Floppy System, The* A high quality digital mass storage system that can close the gap between cassettes and disks. Uses small tape cartridges, called wafers, that run a lot faster than standard cassettes and have a 64K byte memory. Exatron.

Expansion Board A printed circuit board which accommodates extra components or cards to expand a computer. It is called an expansion chassis if it connects an additional cabinet to the system.

Expansion Interface The expansion port of the Commodore 64 is capable of accepting one cartridge. Some companies manufacture expansion interfaces that enable the user to connect more than one cartridge to the Commodore 64 at one time. See **Cardco**.

Expansion Port Located in the rear of the Commodore 64, the expansion port is a 44-pin port that allows access to the address bus as well as the data bus within the computer. Modules designed to plug into this slot can be pre-programmed in ROM and come up running when the computer is powered on. CP/M modules can be inserted in this slot.

Exponential BASIC. See EXP.

Extended Arithmetic Double-precision floating point operations. Also used to refer to expanded capabilities, such as built-in trigonometric functions.

Extended Background Color Mode The Commodore 64 formats the screen in one of two ways: in a hi-resolution mode or the standard character mode. In the character mode the screen is divided into 1000 squares and formatted as 40 columns by 25 lines. In standard character mode each character must be one of 16 colors and the background is set as one color for the entire screen. In extended background color mode the background for each character can be set independent of the others, and only the first 64 characters are available to the user. This mode is enabled by setting bit 6 of address 53265. See also Character Generator.

External Commands The Command Processor is a program which accepts a command (usually from a keyboard) and causes it to be carried out. Some command processors contain the programming required for all commands they process (internal commands). Others do not carry out any commands directly. Instead, they examine the command, determine what other program (if any) can carry out the command, locate the required external program, and start it running (external commands). Still another type of command processor carries out some commands directly (internal commands), but locates and runs other programs for some commands (external commands).

External Device Port Connections. An address providing a connection between the computer's internal processor and an external device through the computer's ports. Ports are used to attach input and output devices.

External Memory Memory is any device which can store information and allow it to be retrieved when needed. The Commodore 64 relies primarily on Random Access Memory (RAM), Read-Only Memory (ROM), disks, and cassettes. The term Memory, by itself, is usually a reference to RAM. This is the erasable and reusable memory located inside the Commodore 64.

ROM (Read-Only Memory) contains fixed data, usually

Extra Ignored • Extra Practice Spelling

programs such as the Commodore 64's operating system. ROM and RAM together make up the internal memory or main memory of the Commodore 64, or any other computer. Data in internal memory is immediately available to programs for processing.

External Memory—such as cassette, disk, and hard disk—requires mechanical retrieval of data and is hundreds or thousands of times slower than internal memory. Data in external memory must be copied into internal memory (INPUT), processed, then copied back out to external memory (PRINT #).

If data has been created, it can be written out to external memory without a READ first. And, if data read in from external memory has not been modified, there is no need to write it back out since the original copy is still there.

While external memory is very slow relative to internal memory, it does have advantages. It is much cheaper per character of data stored on-line (available for processing without manual intervention). In addition, the ability to store external memory data off-line (on disk or cassettes) allows essentially unlimited storage of data. However, this requires manually inserting the disk, cassette, or disk before the data can be loaded into the internal memory for processing. See also Virtual Memory, RAM, Spool, Memory Map, Bubble Memory.

Extra Ignored Following an INPUT statement in a program the user is required to make an entry and press return. If the INPUT statement is expecting only one variable (INPUT A) and the user enters two, the second will be ignored.

Extra Practice Spelling Series* A word is displayed on the screen while the student is asked to key in the word. After he has successfully done so, the word disappears from the screen and he is asked to key in the word from memory. When he has correctly spelled the word from memory, a new word is presented on the screen. After each lesson the student's performance is rated and if he has spelled at least 10 words from memory without error, he is rewarded. There are over 7000 words available. FET Pronounced "fett". Field Effect Transistor. A transistor with an n-type silicon bar for the main conduction path and depletion layering for control.

Fetch Cycle The first cycle in the fetch-decode-execute sequence of instruction execution. During the fetch cycle, the contents of the program counter are placed on the address bus, a Read signal is generated, and the Instruction Pointer is incremented. The data bytes arriving from the memory (the instruction which has been fetched) will be gated into the Instruction Register of the Control Unit.

Fetch-Ahead See Carry-Look Ahead.

FFFF The hexadecimal representation of the maximum simple address value on 8-bit microcomputers: FFFF base 16 = 65535.

FFT A fast computational algorithm for determining the Fourier curve fit to a collection of data points

Field A logical grouping of data. This could be a group of related characters in a record (name field), a work area in memory, or in the CPU a zone within an instruction, such as opcode, address, or comment.

FIFO Pronounced "fife-oh". First-In-First-Out structure. Data is added at one end and removed from the other, like cars lined up at a gas station. A FIFO buffer is used to connect two devices operating asynchronously at different speeds. Each device is connected to one end of the FIFO buffer.

File A logical grouping of information with an identifying name (considered a unit by a user). A file may be divided into records, blocks, or other units as required by the memory device.

File, Fragmented See Fragmentation.

File Control Block An area of memory used by a Disk Operating System to keep track of a file's status, including such information as I/O status, current record, physical sector numbers, etc.

File Exists An error message from the 1541 disk drive generated when the user attempts to save a program by a name that already exists on the disk.

File Management • Fixed-head Disk

File Management Disk Maintenance. File management or disk maintenance is record keeping on disks. This includes creating files, finding them by name, ensuring that adequate free space is available on the disk, maintaining backups, and deleting files no longer needed. These functions are supported by the various DOS functions, but require thoughtful planning by the user to insure proper results.

Some data base management (DBM) systems attempt to automate part of the work of keeping track of files and disks. Some DBM systems maintain files of control and tracking data on other files and disks, and may provide alternatives to DOS functions.

File Management/Handling Software See Solver, The; Media Register; Name Machine, The; Research Assistant 2.0; SuperTerm.

File Not Found An error message from the 1541 disk drive generated when a user attempts to access a file that does not exist on a particular drive or disk. Be sure the file being accessed is spelled correctly and in the exact format as the one on the directory. This message may also be generated when the disk is not in the drive, or when it hasn't been properly initialized.

File Not Open If you attempt to use the commands CLOSE, CMD, PRINT#, INPUT#, or GET# with a file that was not already properly opened, this message will appear.

File Open Indicates that you attempted to open a file that is already open. Remember to keep file numbers, device numbers, and channel numbers straight.

File Separator A special pattern of bits or frequency which separates one file from another on magnetic media such as tape or disk.

File Specification (or Filespec) The complete specification of a file, including file name, drive identifier, and extension.

Filewriter/Filereader* User can write data files with output on either screen or printer. Cassette. RAK Electronics.

Filing Assistant, The* Database. The Filing Assistant is a general purpose database management system for the Commodore 64. The system package comes with an easy-to-follow manual and a program disk. A series of programs are provided that are required to build the various functions of the system. The software supports a variety of printers, and a special menu option is available to set up the desired printer configuration. A user-defined format is created for all the records in a file. The program uses random files to store records. Each record may contain a maximum of 25 fields and a total of 254 characters. Since field names and

formats are stored in a separate file, all of the record capacity is available for data entry. The main program is menu-driven and utilizes the Commodore 64's special function keys to access functions. One of the highlights of the program is the command/option line at the bottom, which prompts the user for a specific command and displays the options available. In the CHANGE/UPDATE mode, records may be Added, Deleted, or Sorted (by user-specified key fields), and Searched, Copied or Browsed using the function keys. A special program for generating reports is loaded from a disk when a report of the entries is desired. This program presents many special features such as automatic page-numbering, headers, and footers. Additional options are available for printing pre-formatted mailing lists. The program files can be merged with the word processor—The Writer's Assistant—to produce customized form letters. Rainbow Computer Corporation.

Firmware A program stored in a ROM. Originally, firmware was used only for microprograms inside the CPU. In microprocessors, many kinds of programs reside in ROM, and firmware designates any ROM-implemented program.

Fixed Media for Recording Information The physical devices for recording information, such as programs and data files, are called media. The main medium for the Commodore 64 is disk, but cassette, hard disk, RAM, ROM, and other devices are also used. Media are often classified as:

a) removable media—such as disks, cassettes and some hard disks or

b) fixed media—such as most hard disks. Fixed media are not removable from the device that drives them, so there is no ability to store additional data or backup copies off-line (outside the computing system) for insertion when needed. See also Memory.

Fixed Point Integer representation with the decimal point assumed to be in a fixed position. Contrast with floating point.

Fixed-Head Disk Disk system with a head over each track. Elimination of head positioning delay time provides very high speed access, but at high cost.

Flag Status indicator for a special condition. A flag is normally stored in a flip-flop or in a register. Typically, a microprocessor provides at least the following status flags: carry, zero, sign, overflow, and half-carry or auxiliary carry.

Flag Bits See Status Register.

Flash Spell Helicopter* Elementary and junior high school students learn to spell any word entered into the data system. The word is flashed on the screen for half a second at a time while the student tries to spell it. For words spelled right the first time, the student receives ten seconds helicopter (game) time. An additional game may be played after earning time in the spelling game. Cassette or disk. Microcomputer Workshops.

Flip-Flop Circuit used to store one bit of information. An FF is bistable with two stable states (0 and 1). Registers are generally assembled out of flip-flops.

Floating Gate Technique used for UV-erasable EPROMs. A silicon gate is isolated inside the silicon dioxide.

Floating Point Constants. The Commodore 64 represents numbers as either integers (whole numbers 1, 2, etc.) or floating point numbers which may contain fractions. A floating point number is expressed in decimal notation or in scientific notation. In decimal notation, nine digits can be displayed on the screen, giving a maximum value of 999999999. If you do not include a decimal point, one is presumed to follow the last digit. Numbers larger than 999999999, or smaller than .01 are printed on the screen in scientific notation. On the Commodore 64, the largest number represented is 1.70141183E+38, and the smallest number represented is 2.93873588E-39.

Floating Point Variables. Variables are names that represent numbers. Any name that is not followed by a symbol % for integer or \$ for string variable is assumed to represent a floating point constant on the Commodore 64. It is important to identify integers when possible, as they only take up two bytes in RAM, whereas the floating point takes up five bytes.

Floating Point (Representation) Representation of numbers in a fixed length format. The number N is normalized and encoded as a mantissa field M and an exponent field. The name reflects the fact that the representation remains fixed as the decimal point floats, i.e., the changes in magnitude are reflected by adjustment of the exponent field with renormalization of the mantissa field. The precision of the representation is limited by the number of bits allocated to the mantissa field. Contrast with Fixed Point.

Floppy Disk A mass-storage device. Flexible (floppy) mylar disk (disk) on which information is recorded. The 8 inch disk is sealed in a square plastic jacket lined with a soft material which cleans the disk as it rotates. A cut-out slot provides access for the moving head which must actually come in contact with the disk surface in order to read or write. Other holes in the jacket provide access to sector index holes in the disk. Disks are hard-sectored if

the sector start points are marked by holes in the disk. Soft-sectored disks have only one (or a few) holes to mark the start of the track. The sector start marks are placed on the soft-sectored disk under software control in a process known as formatting. See Disk.

Disks are also classified as single or double sided, single, double, or quadruple (quad) density. See these entries.

Floppy Mini Floppy that is 5-1/4" square. This is the standard size for the Commodore 64.

Flowchart Symbolic representation of a process. Boxes represent commands or computations. Diamonds represent tests and decisions (branches). A flowchart is a useful step between process specification and program writing. Flowcharts facilitate understanding and debugging a program by segmenting it into logical, sequential steps.

FN BASIC. This statement references a previously defined formula established with a DEF FN statement. The format is:
10 DEF FN <name> (<var>)=<equation> 20 PRINT FN <name> (<num>)

<name> is of one or two characters assigned by the user. It must begin with a letter. It is then referenced by the FN statement.

<var> is any variable assigned by user.

<num> is the number that will be substituted into the formula in place of the variable.

FOR and NEXT BASIC Statements. The FOR statement, used in conjunction with the NEXT statement, performs a series of instructions in a loop a given number of times. The format is:

FOR <variable> = <X> TO <Y>[STEP <Z>]

.

NEXT [<variable>,variable...]

<variable> is an integer variable to be used as a counter.

<X> is a numeric expression which is the initial value of the counter.

<Y> is a numeric expression which is the final value of the counter.

<Z> is a numeric expression to be used as an increment.

Within a single FOR ... NEXT loop, all lines following the FOR statement are executed until the NEXT statement is encountered. Then the counter <X> is incremented by the amount specified by the STEP value <Z>. If you don't specify a value for <Z>, the increment is set to one. A check is then done to see if the value of the counter is now greater than the final value <Y>. If it is not greater, BASIC goes back to the statement after the FOR statement and the process is repeated. If it is greater, the first statement following the NEXT statement is executed.

If the value of <Z> is negative, the check is reversed. The counter is decremented each time the loop is executed and execution continues until the counter <X> is less than the final value <Y>.

Foreground Program • FRE

The statements within the FOR...NEXT loop are not executed if $\langle X \rangle$ is already greater than $\langle Y \rangle$ when the STEP value is positive, or if $\langle X \rangle$ is less than the $\langle Y \rangle$ when the STEP value is negative. If $\langle Z \rangle$ is zero, an infinite loop will occur unless you provide some way to set the counter greater than the final value.

A nested loop is one FOR...NEXT Loop placed inside another. A third loop can be placed within the second, and so on. Whenever FOR...NEXT loops are nested, each loop must have a unique variable name as its counter. The NEXT statement for the inner loop must appear in a statement before the NEXT statement for the outside loop. However, if nested loops have the same end point, a single NEXT statement may be used for all of them. The format is:

```
NEXT <variable1>,<variable2>,<variable3>
```

which is the same as

```
NEXT <variable1>
NEXT <variable2>
NEXT <variable3>
```

The variable or variables in the NEXT statement may be left out. In this case the NEXT statement returns to the most recent FOR statement. When using FOR...NEXT loops, you should include the variable or variables on all the NEXT statements. It is a good rule of thumb to use variable names on all NEXT statements in order to avoid confusion.

When a NEXT statement is encountered before its corresponding FOR statement, a "NEXT without FOR" error is displayed. Here is an example:

```
READY
10 M=2:K=10
20 FOR I=M TO K STEP 2
30 PRINT I;
40 NEXT
RUN
2
4
6
8
10
READY
```

FOR...NEXT statements function differently in Compiler BASIC. For more information see your Compiler Manual.

Foreground Program In a multi-programming environment, a foreground is a higher priority program. It is also a program in charge of interfacing with a user or process.

FORMAT Predesigned arrangement of data. Arrangement of elements of a command or statement, the order of data in a file, or the layout of a printed document.

Formula Too Complex A limited number of characters can be used in a string expression. This error message indicates the encountered expression has too many characters. It can also mean that too many parentheses are being used in a formula.

Fort Apocalypse* Defeat the evil lords and free their prisoners by planning a strategy for your fuel and weapons use. Synapse.

FORTH Programming language and operating system. FORTH is characterized by threaded code and postfix, or reverse Polish notation. FORTH is an extensible language: you can create new commands, defined in terms of the existing commands or in Machine language. Your new commands then become part of the FORTH language. This allows you to create your own commands suitable for a specific purpose. FORTH is also highly transportable from one microcomputer to another—more so than BASIC and most other languages. FORTH runs fast (it is closer to Machine Code than to higher level languages like BASIC). FORTH may be somewhat harder to master than BASIC, but it offers many advantages.

FORTRAN FORMula TRANslator. One of the first high level languages, still widely used by scientists and engineers. BASIC is largely based on FORTRAN, using statement numbers and a similar set of commands. The differences are slight, mostly dealing with I/O statements. FORTRAN includes the FORMAT statement for formatting printed output. It is rich in mathematical functions and supports an extended precision calculations mode for scientific problems.

FORTRAN is a compiled language, not interpreted like BASIC. A program is edited in a file, then submitted to a compiler for translation into executable object code. FORTRAN and BASIC are so similar that BASIC could be called an interpreted dialect of FORTRAN. Here is a FORTRAN program to sum the first 100 integers:

```
20FOR I = 1 TO 100
30J = J + I
40NEXT I
50END
```

Forty Fathoms* Dive for sunken treasure and encounter the creatures of the deep. Commodore.

Fourier Transform The mathematical analysis of a complex wave-form into harmonic components.

FPGA Field Programmable Gate Array. A device containing an array of AND and OR gates which can be re-connected (programmed) in the field (i.e., without return to the factory).

Fractions Package* Seven of the Micro-Ed math programs at a reduced price. Includes Parting Shots, On the Line, Tutti Frutti, and more. Cassette. Micro-Ed.

Fragmentation When mass memory has been allocated in such a way that it has many unallocated areas (fragments) that are too small to be useful. The remedy is to combine all of the small areas into one large usable area. See Validate.

Frame The necessary underlying structure for a record, file, or other data item. The frame creates an organization within which the data takes its place.

FRE BASIC Function. FRE will return the number of available bytes in memory that are not being used by the operating system. If the number returned is negative, add 65536 to determine the number of free bytes.

The format is:

FRE(0)

Example:

Print FRE(0)

-26627

READY

Frequency The number of cycles per second. $F=1/T$, where T is the period, in seconds, over which cycles are counted.

Front Panel A panel with lights and switches to display information and allow direct control or access to memory or registers. A front panel requires a specific interface and a monitor program. Many microcomputers have no front panel, therefore access is from a keyboard and screen.

Front-End Processor A processor which acts as an interface with a user or a process. The front-end may perform pre-processing translations or file handling, while the main processor performs interpretation, execution, or other processing.

Full Duplex Communication technique which allows simultaneous transmission and reception of data.

fullFORTH* This program offers enhanced fig-FORTH complete with conditional assembler, interpreter, floating point, editor, and strings. A target compiler can also be added at an extra charge. Microtech.

Fun Predictions* Calculates your age to the minute and predicts your future in a congenial manner. Comm*Data Computer House.

Function keys Keys located to the right of the Commodore 64 keyboard labeled F1, F2, F3, F4, F5, F6, F7, F8. They are available for user assigned functions. Each key has a separate CHR\$ code number (from 133 to 144 inclusive). A user can input a character from the keyboard and compare it to the CHR\$ code number. If there is a match, the program will know one of the function keys has been pressed and can branch to an appropriate subroutine. For example:

```
10 GET A
```

```
20 IF A=133 THEN GOTO 400
```

400 is a subroutine that may, for example, print hello. If F1 is pressed at this time the word hello will appear on the screen.

Fundamental The base or carrier signal on which a data signal will be superimposed. Usually a pure sine wave with no distortion.

That information can be read by accessing memory address 56320 for port A and 56321 for port B. See Complex Interface Adapter.

GEMINI-10X* Gemini-10X (and Gemini-15) is a dot-matrix printer that may be used with the Commodore 64 with the aid of a Centronics parallel printer interface. The printer features 120 cps print speed, bidirectional logic seeking carriage control, 9 x 9 dot matrix (with true lower case descenders) and high-resolution bit imaged graphics capability. It has built-in international, block graphic and italic character sets. In addition, 2K RAM memory is available for downloading a user-defined character set. GET BASIC Statement. This statement is used in a BASIC program to take one character from the keyboard buffer and assign it a name. The format is:

GET <var>

<var> follows variable rules. It can represent a number or a string character. If the variable is identified as a number (it does not have a \$ following it) then entry from the keyboard must be a number (an alphabetic character would give an error message.)

GET# BASIC Statement. This statement is similar to a GET statement, except the number or character obtained may be from a device other than the keyboard. The GET# must reference a file already opened and the variable assigned (either numeric or string) must correspond to the one received. The format is:

OPEN <num>,<dev> GET#<num>,<var>

<num> is an arbitrary number from 1 to 127 that is used to reference the open file on device <dev>.

<var> is the variable and follows normal variable rules. It must begin with an alphabetic character and only the first two characters are read. If it is declared as numeric the data that is taken in must be numeric.

GETIN The name of a Machine language subroutine within the operating system of the Commodore 64. It is one of the subroutines referred to as the KERNAL and used to handle input/output operations. By jumping to address \$FFE4, GETIN moves one byte from a channel to the accumulator. When data is moved from the keyboard queue to the accumulator, a 0 will be loaded if the keyboard queue is empty. See also KERNAL.

Glitch A pulse or burst of noise. A small pulse of noise is called a snivitz. Glitches are more dangerous types of noise pulses which cause crashes and failures.

Global Variable A variable whose name and value are accessible throughout the program or application system: in contrast to a local variable, accessible only within the block where it is defined.

GND GrouND.

Gortek and the Microchips* Learn to program and use your computer with a science fiction story and a four color text. Commodore.

GOSUB BASIC Statement. GOSUB is used in conjunction with RETURN. It is used to branch to and return from subroutines. The format is:

GOSUB<line#>

```

.
.
.<line#> ' begin subroutine
.
.

```

RETURN

<line#> is the line number of the first line of the subroutine. You can call a subroutine using GOSUB any number of times in a program, even from within another subroutine.

The RETURN statement makes BASIC branch back to the statement following the GOSUB statement from which it exited. A subroutine may contain more than one RETURN statement, if you want to return from different points in the subroutine. You may place subroutines anywhere in a program.

In order to keep your program from entering a subroutine that should not be executed, it may be necessary to use a STOP, END, or GOTO statement to direct program control around it.

GOTO or GO TO. A branch instruction in a high-level language.

GOTO Basic Statement. Used to exit from the normal program sequence to a specified line number. The format is: GOTO<line>

<line> is the line number in the program you want to execute next.

<line> specified after GOTO will be executed if it is an executable statement. If <line> is a non-executable statement, such as DATA or REM, then the program will continue until it finds the first executable line after that.

Graphics Refers to the generation of pictures or diagrams onto the screen or printer. The quality of a graphic display depends on the available resolution. Each one of these pixels can be turned on or off to generate high quality graphic images.

Hard Copy Printed version of a program or file.

Hard Disk A disk composed of a magnetic coating applied to a rigid substrate, such as aluminum or ceramic. The term is used in contrast with "soft" (floppy) disks, which are flexible. Hard disks are faster and have more storage capacity.

Hard-sectored Describes a disk whose recording surface has been divided into sectors using non-alterable methods, such as a ring of holes in the disk itself. The Commodore 64 uses soft sectoring, done by the DOS NEW command.

Hardware vs. Software Computer programs of all kinds are called software. Usually software is contrasted to hardware—the actual chips, wires, boards, etc which make up the computer. In the special case of Read-Only Memory (ROM), this terminology can be confusing and inadequate. A BASIC ROM, for instance, is a ROM (hardware) containing a copy of a BASIC interpreter program (software). Such ROMs are often called firmware to distinguish them from non-program hardware and from software in changeable media (RAM, disk, cassette, etc.).

Harmonic An integer multiple of a fundamental frequency.

Harmonic Distortion Distortion due to the signal's non-linear characteristics, resulting in output which includes harmonics of a harmonic-free sine input.

Harmonics Sound (Waveform). Harmonics are sine waves that are integer multiples of the fundamental frequency of a given note. Depending upon the harmonics in a wave, it can be classified as Triangular, Rectangular, or Sawtooth. See Triangles, Triangular Waveform, Rectangular Waveform, Sawtooth Waveform.

Hes Mon 64 A Machine language monitor for the Commodore 64. Comes with a user's manual intended for people who are unfamiliar with the uses of a Machine language monitor. The program consists of single character commands that may be followed by one or more parameters (such as memory addresses). These commands are available to exit to BASIC (transfer the program control to the BASIC Interpreter) as well as reenter Hes Mon. A simple assembler is included to allow the user to enter short Machine language programs. The monitor allows a programmer to PEEK into the computer's memory and change the corresponding values at these locations, which is useful for Machine language programmers interested in testing/debugging Machine language subroutines. Cartridge. HES.

Hexadecimal Hexadecimal refers to base 16. Frequently abbreviated as hex, this notation is popular with Machine language programmers. It provides the ease of entering address locations in Machine language routines through a monitor.

High Resolution Graphics. The Commodore 64 has two modes of video display: standard character mode and high resolution mode. High resolution mode (Bit Map Mode) on the Commodore 64 is selected by POKEing the appropriate value at address 53265 (the VIC II control register). It may be used to draw highly detailed pictures on the screen. It has useful applications in art or business. In high resolution mode the screen is transformed into 64,000 dots of light (pixels) that are individually programmable. See also Bit Map Mode.

High Seas* Sail the seven seas in search of pirates and treasure. Cassette. Briley Software.

HIRAM The name of a control line that banks an 8K block of memory in and out of the microprocessor's memory. When HIRAM is high the microprocessor sees 8K of KERNAL ROM from \$E000 to \$FFFF. When it is low the microprocessor sees 8K of RAM in that space.

Holding Register A register that holds data temporarily to bridge a speed or timing gap between two devices.

Homonym Machine* Provides exercises using words that sound the same but have different meanings. For elementary students. Cassette. MicroEd.

Human Engineering Friendly Programs for the Operator (User). When writing a program for others to use you must give clear prompts for every item of input data, freeze the screen long enough for them to read or act on the information displayed, and provide clear error messages for incorrect entries. This is referred to as "human engineering"—making the program easy to use as well as technically correct. Another term for this type of programming is making the program "user friendly."

There are several other guidelines for writing user friendly programs. If a complex series of data items has been typed in but some entries are invalid, the user should be able to re-enter only the bad items. Error messages should indicate not only that an entry is invalid, but also, what's wrong with it, and, if at all possible, some hints as to how to correct it (such as a list of possible correct values)

I Codes. ASCII = 73, CMB ASCII = 73 or 201, HEX = 49. i—ASCII = 105, CBM ASCII = 73, HEX = 69. Screen code = 9 or 73. See CBM ASCII.

I See Initialize.

IC See Integrated Circuit.

Identifying Complete Sentences* Find the complete sentences among the sentence fragments on the screen. For elementary school students. Cassette. Micro-Ed.

IEEE Bus The IEEE 488 Bus, often referred to as a GPIB, is a standardized cable with specific handshaking sequences. This standard cable, agreed upon by an international committee, allows any IEEE device to connect and work with any computer that is also set up for IEEE. The GPIB allows for more than one device to connect to the same cable with some limitations on the cable length. Many of the disk drives and some printers that are compatible with the Commodore 64 are IEEE devices. An IEEE interface is necessary to make that connection. See Interface—IEEE.

IF BASIC Statement. Makes a decision regarding program flow based on the result of an expression. The formats are:

IF <expression>[,] THEN <clause>

IF <expression>[,] GOTO <line>

<expression> may be any numeric expression.

<clause> may be a BASIC statement, a sequence of statements separated by colons, or the number of a line to branch to.

<line> is the line number of a line that exists in the program.

If the value of <expression> is not zero (true), the THEN or GOTO clause is executed. THEN may be followed by a line number for branching or one or more statements to be executed. GOTO is always followed by a line number.

If the value of <expression> is zero (false), the THEN or GOTO clause is ignored and execution continues with the next executable statement.

When you enter an IF...THEN statement in direct mode, it directs control to a line number. If you haven't already entered a line with the specified number an "undefined line number" error message is displayed.

Illegal Direct The INPUT statement can only be used in program mode (with a line number). If you attempt to use it in direct mode, this message will appear.

Illegal Quantity If the number used as the argument of a statement is out of the allowable range, this error message will appear. Be careful with variables in a program; they may exceed limits and interrupt the program execution.

Illegal Track or Sector An error message from the 1541 disk drive incurred when the drive attempts to access a track or sector which is not available or does not exist.

Immediate Addressing Mode See Addressing Modes.

INC INCRement Memory. An Assembly language instruction for the 6510 microprocessor that increments the contents of the memory address in the argument by one. The result of increment is then placed in the same memory address and can alter the sign bit flag and the zero flag bit. The accumulator contents are not altered.

Index Disk Directory. The 1541 Disk Drive maintains an index or directory of all files on each disk. The available space in the directory is what limits the number of files on a disk.

Index Registers The 6510 contains, among others, two 8-bit registers (the X register and the Y register). These are involved in many of the Machine Code instructions. In some instructions they are used as automatic offsets to some specified address and are therefore referred to as index registers. An example is the instruction

```
LDA $2500,X
```

In this instruction the address \$2500 is added to the contents of the X register. The contents of that new address (\$2500+x) is then loaded into the accumulator.

Indexed Sequential Access Method A program or package that supports files organized with one or more indexes. Records may be retrieved from the file either sequentially or randomly by the key used in the index.

Indirect Addressing Mode See Addressing Modes.

Info-Designs, Inc. See Management Accounting Systems.

Infomast* General purpose information control program (database management system) for the Commodore-64. Comes with a database, an integral word processor, and a built-in programmable calculator. The incorporation of these three features in one package make it useful in maintaining records, mailing lists, invoicing, and ledgers. Documentation is included with step-by-step instructions for using the features of the database, the calculator, and the word processor. Information is stored in the form of records, each containing a maximum of 255 characters, with user-defined formats. Storage of each record utilizes relative files, a feature that increases the efficiency of sorts

Initialize • Integer Variables

and speeds up the updating process. Sorts and searches on records may be made by "key" field, partial/full string, or multiple fields. Print options are available to print the records in a user-defined format. The programmable calculator mode has limited applications in accounting and statistics. The user can program calculations to be made on a desired number of records. Save option for the calculator program allows the operation to be repeated at will. The word processor is accessible from the main menu and contains full editing/printing features. Merge option allows merging of records with text in the word processing mode. Rabbit Software, Ltd.

Initialize Disk Command. When sent through the command channel, this returns the disk drive to the same state as when powered up. The command is useful when an error condition prevents you from proceeding with disk operation. Also used to initialize a disk (read the Block Availability Map(BAM)) when it is first accessed. The Commodore 1541 disk drive automatically initializes a disk the first time a program or a file is loaded from it. The format is:

```
OPEN15,8,15 PRINT#15,"INITIALIZE"
```

INPUT BASIC Statement. INPUT statement receives input from the keyboard during program execution. The format is:

```
INPUT["prompt";]<variable>[,<variable>...]
```

["prompt"] is a string constant which will be used to prompt for the desired input. For example "Press Any Key".

<variable> is the name of the numeric or string variable or array element which will receive the input.

When the program encounters an INPUT statement, it pauses and displays a question mark (?) on the screen to indicate that data is to be typed in. When a "prompt" is included, this string is displayed before the question mark.

The data that is entered is stored in the variable or variables declared in the variable list. Each data item that is typed in must be separated by commas, and the number of data items must match the number of variables in the list. The type of each data item that you enter in must also agree with the type specified by the variable name (string or numeric). Strings entered in response to an INPUT statement don't need to be surrounded by quotation marks unless they contain commas or significant leading or trailing blanks.

Input/Output See Input, and Output.

INPUT# BASIC Statement. INPUT# reads data items from a file and assigns them to program variables. The format is:

```
INPUT# <filenum>,<variable>[,<variable>...]
```

<filenum> is the number used when the file was opened for input.

<variable> is the name of a variable that will have an item in the file assigned to it. It can be a string or numeric variable, or an array element.

The file may be located on disk or cassette; it may be a sequential data stream from a communications adapter. The type of data in the file must agree with the type specified by the variable name. No question mark is displayed with INPUT# (unlike INPUT statement).

The data items in the file must appear just as they would if the data were being typed in as responses to an INPUT statement. For numeric values, leading spaces, carriage returns, and line feeds are ignored. The first character encountered that is not a space, carriage return, or line feed is assumed to be the start of the number. The number ends with a space, carriage return, line feed, or comma.

If BASIC is scanning the data for a string item, leading spaces, carriage returns, and line feeds are also ignored. The first character found that is not a space, carriage return, or line feed is assumed to be the start of the string item. If this first character is a quotation mark (") the string item will consist of all characters read between the first quotation mark and the next quotation mark. If the first character of the string is not a quotation mark the string is an unquoted string; it will end with a comma, carriage return, or line feed, or after 255 characters have been read. If end of file is reached when a numeric or string item is being input the item is cancelled.

INST/DEL Pressing the INST/DEL key moves the cursor to the left one space and deletes any character the cursor encounters. Holding the key deletes in rapid succession. Pressing the key in conjunction with the shift key moves all text to the right of the cursor one space to the right and inserts a blank space. Holding the key down does the same thing in rapid succession.

Instruction A statement that causes a computer to carry out a specific action. A command differs from an instruction in several ways. A command is usually a complete specification of an action, while instructions are usually combined in dozens or hundreds to make a useful program. Commands are usually acted upon immediately by the computer, while instructions are saved for later execution in a program. Commands are acted on by the basic operating system of the computer, while instructions must be processed by a particular program such as the BASIC interpreter, a FORTRAN or Pascal compiler, etc. See Command Processor, DOS.

Instruction Register In most MPU's the IR contains the address of the next instruction to be executed. Branches are implemented by loading a new value into the IR.

INT BASIC Function. INT function returns the largest integer that is less than or equal to <x>. The format is:

```
<variable> = INT(<x>)
```

<x> is any numeric expression.

For example:

```
PRINT INT(57.97) returns 57.
```

```
PRINT INT(-4.53) returns -5.
```

Integer Constants An integer is a whole number (1,2,3 etc.) without a fraction or decimal point. Integers are stored on the Commodore 64 as 2 byte binary numbers and can range from -32768 to +32767. They take up two bytes of memory when stored in RAM and should not contain any commas.

Integer Variables A variable is a character or group of characters that are used to represent a specific value. On

the Commodore 64 when a variable is used to represent an integer, the variable must be followed with a percent (%) sign. The variable may be any length but only the first two characters are considered by the Commodore 64. The variable must begin with an alphabetic character and be followed by either a letter or a number. The constant must always match the variable. If you declare the variable as an integer, the constant can not be a decimal number. Variables cannot be any of the keywords, such as a BASIC command.

Integers I* Problem solving in addition and subtraction, including graphs and axis. Tests junior high school students. Cassette. Comm* Data Computer House.

Integrated Circuit A complete electronic circuit with multiple components (translators, diodes, resistors, capacitors, etc.) all constructed on a single small silicon chip.

Interbus Series, The* These three interfaces include the VIE and CIE which are IEEE 488 interfaces. When plugged into the expansion port peripherals can be attached without any interference. The V232 and C232 are serial interface cartridges that will allow you to plug into modems, plotters, and printers. The VPI and CPI are parallel interfaces that provide direct BASIC use of the parallel printer bus and give "invisible" access to the bus. Micro Systems Development, Inc.

Interface The point at which two systems make contact. Most microcomputers have multiple interfaces or "ports," such as a serial port to connect serial devices, a parallel port, and possibly TV or monitor ports, power port, joystick ports, etc. Interface is also used to refer to the type of interconnection, with respect to its size or shape (subminiature 25-pin D connector), its mode of function (serial, parallel, etc.), or its electrical characteristics (RS-232, IEEE, etc.).

Interface—IEEE With a proper interface, the Commodore 64 can be connected with an IEEE device. The interface generally connects with the computer through the serial port or expansion port and contains a cable with one end compatible with the Commodore 64 port and the other end compatible with the IEEE port. The Commodore 64 must be set up with special instructions since a specific handshaking sequence is required in transferring data to an IEEE device. These instructions are either programmed into the IEEE interface or loaded into the Commodore 64. There are many more advanced disk drives and printers from Commodore that require an IEEE interface to connect to the Commodore 64. See Interpod, Link.

Interface—RS-232 The Commodore 64 allows for the connection of RS232 devices (most modems and some printers) through the user port. However, the port cannot be connected directly with such a device. An interface is necessary to alter some voltage discrepancies between the user port and an RS-232 device. There are a number of products available for this, including those from Commodore, Richvale Telecommunications (See Link), and Oxford Computer Systems (See Interpod).

Interface Boards See Auto Clock, The; Card "?" Card/Print; Cardette; Connection, The; CX-6401 Interface; CX-6402 Interface; Expander Boards; Expandoport Series; Interbus Series, The; Minibus; Modem Interface; MW-302-Parallel Printer Interface; Universal Input/Output Board; Universal Tape Interface & Duplicators.

Interference Occasionally a television used as a video display unit is subject to interference—wavy patterns or lines on the screen. This can sometimes be remedied by moving the TV, keyboard, or power supply. The Commodore 64 allows for two channel selections (3 or 4). If one channel is receiving interference you can try the alternate channel with the switch in the back of the Commodore 64.

Interpod* Enables the Commodore 64 to connect with RS-232C and IEEE devices. The Interpod comes with its own power supply and connects to the Commodore 64 through the serial port normally connected to a 1541 disk drive. The Interpod has a second serial port to allow for the connection of a 1541 drive, if desired. The Interpod has its own internal set of keywords to allow the user to set important parameters for RS-232 communications. Included are baud, parity, chrsize (character size), crdelay (carriage return delay), stopbits, break, unbreak, change (to change Interpod's command channel and RS-232 port), clear (to clear buffers), convert (to convert CBM ASCII to standard ASCII), and unconvert (cancel convert). Cables to connect RS-232 devices or IEEE devices are not included. Hardware. Oxford Computer Systems.

Interrupt A signal to an MPU that an event has occurred which requires attention. The MPU will save enough information to resume the task it is currently working on, then execute code from an interrupt servicing program. There may be multiple interrupt lines or other ways of distinguishing interrupts, in which case the MPU can tell by which interrupt signal it receives what kind of event has occurred.

Interrupt—Machine Code The 6510 has two interrupt lines, the Interrupt ReQuest (IRQ) line and the Non-Maskable Interrupt (NMI) line. When the IRQ line is activated (and the interrupt flag bit is not set), a series of operations is automatically performed by the microprocessor. The microprocessor first completes whatever instruction it is currently executing. It sets the interrupt flag bit to prevent any further interrupts. It pushes the program counter and the status register onto the stack. The microprocessor fetches the contents of memory location FFFE and FFFF. This memory location contains the address (or interrupt vector) to which the microprocessor will branch. The NMI line works in the same fashion, but the interrupt flag bit can not prevent this interrupt. The NMI line fetches its interrupt vector from FFFA and FFFB. Thereafter, when the microprocessor encounters an RTI instruction, it pops the program counter and status register off the stack and resumes the program where it left off.

INX INcrement X register. An Assembly language instruction for the 6510 microprocessor that increments the contents of the X register by one. The result is then placed in the X register and can affect the sign flag bit and the zero flag bit. The accumulator is not affected.

INY INcrement Y register. An Assembly language instruction for the 6510 microprocessor that increments the contents of the Y register by one. The result is then placed in the Y register and can affect the sign flag bit and the zero flag bit. The accumulator is not affected.

IOBASE A Machine language subroutine within the operating system of the Commodore 64. It is part of a group of subroutines referred to as the KERNAL and used to handle input/output operations. By jumping to address \$FFF3, IOBASE moves the address of the start of memory mapped I/O devices into the X register (lower address byte) and Y register (high address byte). This address can then be used with an offset for accessing all I/O registers. See KERNAL.

J Codes. ASCII = 74, CBM ASCII = 74 or 202, HEX = 4A.

JMP JuMP to address. An Assembly language instruction for the 6510 microprocessor that places the address specified by the argument into the program counter. The next instruction executed will therefore be that which is located by the argument. The addressing mode of the argument can be absolute or indirect. None of the flag bits are altered.

JSR Jump to SubRoutine. An Assembly language instruction for the 6510 microprocessor that saves the current location onto the stack and then loads the address specified in the argument into the program counter. The next instruction executed will be that which is located by the argument. Thereafter, if the program encounters a RTN (return), the address saved on the stack is put back into the program counter and the program returns to the instruction that follows the JSR. The addressing mode of the argument must be absolute and none of the flag bits are altered by this instruction.

Commodore Electronics, Ltd.

Justify To make the edges of a text file line up straight. Left justification is almost universal in English text. Right justification is usually present only in text that has been typeset or processed by a word processor or special typewriter to insert a variable amount of space between words or letters (proportional spacing).

The first part of the document is a list of names and dates, which appears to be a roster or a record of some kind. The text is very faint and difficult to read.

The second part of the document contains several paragraphs of text, which are also very faint and difficult to read. It appears to be a narrative or a report of some kind.

The third part of the document contains several paragraphs of text, which are also very faint and difficult to read. It appears to be a narrative or a report of some kind.

The fourth part of the document contains several paragraphs of text, which are also very faint and difficult to read. It appears to be a narrative or a report of some kind.

The fifth part of the document contains several paragraphs of text, which are also very faint and difficult to read. It appears to be a narrative or a report of some kind.

K Codes. ASCII = 75, CBM ASCII = 75 or 203, HEX = 4B. k—ASCII = 107, CBM ASCII = 75, HEX = 6B. Screen code = 11 or 75. See CBM ASCII.

K Byte is a label for storage that holds one character (letter, digit, etc) in computer memory or disk. Abbreviated B or in thousands KB, or simply K. Actually, 1K = 1024 bytes because this is an even power of 2. Commodore 64 often has 64K bytes (or 64KB) of internal memory, or 64,000 (to be precise, 64K = 64 x 1024 = 65,536 bytes).

KB Measurement of Bytes in thousands. See K.

Kentucky Derby* One of the "Inside BASIC series" programs available for the Commodore 64. It is a game incorporating Sprites, high-resolution Bit Map graphics, and Sound synthesis. The object of the game is to bet on a horse and try to win the most money. Bets may be made on a horse to win, place, or show. The odds given for a horse influence its chances of winning. The Inside BASIC series increases programming skills in BASIC language by showing how each program in the series was developed. The documentation also includes line by line description of the program, suggested changes, a complete program listing and an overview that discusses the step by step development of the program.

Kernal The Commodore 64 is controlled by the 6510 microprocessor manufactured by Commodore. The 6510 is controlled by Machine Code either programmed by a user or internal to the machine in ROM. Even a simple action like hitting a key on the keyboard and having it appear on a screen requires many Machine Code instructions. Since some of the operations occurring between the peripherals and the computers are the same each time, the Machine Code instructions for these operations have been included in ROM and are referred to as the KERNAL. Essentially these are Machine Code subroutines beginning at specific addresses in the memory. One simply jumps to that address and the entire subroutine is executed. As an example, the KERNAL routine called GETIN has a starting address at

\$FFE4. Jumping to that address in a Machine language program will automatically take any character in the keyboard queue and place the ASCII value into the accumulator. After the process is complete, the counter will return to the next line of the user's program. Often some preliminary routines must be executed before a specific KERNAL can be used.

Key Identification The process of detecting which key has been pressed. The two common techniques are:

- 1) Row Scanning; and 2) Line Reversal.

Keyboard In general, microcomputers use one of two types of keyboards:

- 1) The Fully Encoded Keyboard. Supplies the ASCII code that corresponds to the key that has been pressed. Such a keyboard has debounce and multiple rollover protection. See also Rollover, Debouncing.

This type of keyboard is used when a complete set of alphanumeric keys are needed.

- 2) Non-Encoded Keyboard. Generally the simplest type, it consists of a matrix of rows and columns and is read by the resident software.

Keyboard Interfacing The process of connecting a keyboard to the microprocessor system so that the processor is able to detect which key is pressed. An interface should also be able to send the corresponding code of the key that is pressed to the MPU. See also Keyboard.

Keyword A word which has special significance to a program. It must not be misspelled or used for other purposes, or erroneous results may occur.

Keywords Commodore 64 BASIC keywords.

LDA Load Accumulator. An Assembly language instruction for the 6510 microprocessor that places a number into the accumulator. That number comes from the argument or from the memory location specified in the argument. The addressing mode of the argument can be immediate, zero page, zero page X, absolute, absolute X, absolute Y, (indirect) X, or (indirect) Y. The sign flag bit and the zero flag bit are affected.

LDX Load X register. An Assembly language instruction for the 6510 microprocessor that places a number into the X register. That number comes from the argument or from the memory location specified in the argument. The addressing mode of the argument can be immediate, zero page, zero page Y, absolute, or absolute Y. The sign flag bit and the zero flag bit are affected.

LDY Load Y register. An Assembly language instruction for the 6510 microprocessor that places a number into the Y register. That number comes from the argument or from the memory location specified in the argument. The addressing mode of the argument can be immediate, zero page, zero page X, absolute, or absolute X. The sign flag bit and the zero flag bit are affected.

Lease/Buy?* Assists the potential buyer with information to help decide whether to lease or purchase materials and property. Disk; printer required. Powerbyte.

Left Justify See Justify.

LEFT\$ BASIC Function. LEFT\$ function returns the leftmost <n> characters of X\$. The format is:

<string variable> = LEFT\$(X\$, <n>)

X\$ may be any string expression.

<n> is a numeric expression which must be in the range 0 to 255. It specifies the number of characters you want in the result.

If <n> is larger than LEN(X\$), the entire string X\$ is returned. If <n>=0, a string of zero length is returned.

See also LEN, MID\$, RIGHT\$.

Lemans* Pass as many cars as possible while avoiding road hazards and collisions with other cars. This Grand Prix racing game requires paddles for steering control and gas. Commodore.

LEN BASIC Function. LEN returns the number of characters in the string expression X\$. The format is:

<variable> = LEN(X\$)

The count returned includes blanks and unprintable characters.

LET BASIC Statement. LET statement assigns the value of an expression to a variable. The format is:

LET <variable><expression>

<variable> is the name of the variable or array element which is to receive a value. It may be a string or numeric variable or array element.

<expression> is the expression whose value will be assigned to <variable>. The type of expression (string or numeric) must match the type of the variable, or a "Type mismatch" error will be displayed.

The word LET is not necessary in BASIC programs when assigning values to variables. You may simply use the format:

<variable> = <expression>

Line Logical Screen Line. Although information displayed

Line Number • List

on the screen is a maximum of 40 characters wide, the Commodore 64 stores a line of BASIC 80 characters long. If you begin entering a BASIC program line to the screen, you will see the cursor automatically return to a second line and allow you to enter up to 80 characters. The 80 characters entered are considered a logical screen line.

Line Number Largest in BASIC. The largest possible line number for a BASIC program is 65529.

Line Reversal Identifying which key was pressed on the keyboard by interfacing the keyboard with the processor using the PIO (Parallel Input/Output) Interface.

Link On the Commodore 64 a BASIC program can be run in one of two modes: direct mode or program mode. In the program mode each BASIC line is stored in memory in a specific format that includes a link address. The link address consists of two bytes located at the beginning of each line of BASIC. The two bytes make up an absolute address that points to the beginning of the next line of BASIC.

Link Time The point in the processing of a program with a language translator (Compiler or Assembler) when the program is tailored for a specific memory location. This occurs after compiling (compile time) but before execution (execution time). Some small systems do not require linking.

Link* This C-64 Link contains a cartridge that inserts into the expansion port and expands the capabilities of the Commodore 64. With the C-64 Link in place, IEEE devices such as the Commodore 4040 or 8050 disk drives and IEEE printers can be used. With the proper cables, two or more Commodore 64's can be connected to a single disk drive or printer. Each computer must have its own Link and special precautions are necessary when users attempt to access a file, but it affords an excellent opportunity for groups of users, such as in an office or school to share a single disk drive or printer. In addition to serving as an IEEE interface, the Link adds fifteen new I/O commands to the BASIC interpreter. The commands, listed below, facilitate I/O operations. The Link also includes a Machine language monitor which you enter by typing MONITOR and pressing a carriage return. You can then display values at specified memory locations, display register values, execute Machine Code programs from selected locations, and load and save programs to and from selected locations. Interfacing with other devices requires special cables not included with the

Link. Cables available from Richvale Telecommunications include the Link to IEEE device cable, a user port to parallel port cable, and a user port to RS-232 port cable. To access different devices you enter the words SERIAL, PARALLEL, or IEEE from the keyboard. The documentation is helpful and easy to read. The following BASIC 4.0 words are added to the BASIC interpreter with the Link. Richvale Telecommunications.

APPEND reopens a closed sequential file for adding information to the end.

BACKUP creates an exact copy of a disk on a IEEE disk drive.

COLLECT rewrites the Block Availability Map.

CONCAT concatenates two files.

COPY copies a file from one disk to another or to the same disk with another name.

DCLOSE closes a specified file, or all files, if no file is specified.

DIRECTORY or CATALOG displays the directory of a disk.

DLOAD loads a program from disk.

DOPEN opens any file to read, and a sequential or relative file to write.

DS\$ & DS reads the DS\$ and DS variables which specify an error message.

DSAVE saves a file to disk.

HEADER formats a new disk.

RECORD positions the disk to a specified record when using relative files.

RENAME renames a disk file.

SCRATCH eliminates a file from disk.

LISP Programming language that is symbol oriented in the way that other languages are number oriented. The type of data item it handles best is ideally suited to the representation of information whose structure cannot be completely specified in advance. LISP permits the building of intermediate structures and discarding of them without causing the user any worries about how to find and later reuse the space necessary for their storage. The syntax of LISP is simple and elegantly defined. The natural method of building programs in LISP by function composition encourages good programming style and facilitates modular programming.

LIST BASIC Command. LIST command displays the program currently in computer memory, on the screen or other specified device. The format is:

```
LIST [[<line1>]-[<line2>]]
```

<line1>, <line2> are valid line numbers in the range 0 to 65529. <line1> is the first line to be listed and <line2> is the last.

Three options are available when using the hyphen (-):

1. If you type <line1>-, that line and all higher numbered lines will be listed.
2. If you type -<line2>, all lines from the beginning of the

program through <line2> are listed.

3. If you type both line numbers: <line1>—<line2>; all lines from <line1> through <line2>, inclusive, are listed.

For example:

LIST 200-300,

list lines 200 through 300, inclusive.

List Mite 2* Helps you organize your list-keeping chores. You can develop your own format, write and/or read files on tape/disk, display, edit, and search for information that you need to save. Nelson Software.

LISTEN The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFB1, LISTEN will convert a device number to a specific address and then transmit it to the serial bus. If a device with that address exists on the serial bus it will go into a LISTEN mode and be ready to receive data. The accumulator must be loaded with the device number prior to using this routine. See KERNAL, Serial Bus, CMD.

Listener The Commodore 64 utilizes a serial bus to connect to the 1541 disk drive and some printers. Since more than one device may be present on the serial bus it is important that only the intended device receive data. The Commodore 64 arranges for this by making a particular device a listener by sending appropriate command signals with a specific device number. All data sent across the serial data line are received only by the listener until the UNLISTEN command is sent.

LOAD The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFD5, LOAD moves consecutive data bytes from input device into Commodore 64 memory. Prior to using this routine the Accumulator is loaded with 0 if the routine is to load data into memory or a 1 if the data is to be compared with data already in memory. If the input device was opened with a secondary address of 0 then the X and Y registers must be loaded with the address where data will be stored on the Commodore 64. If the secondary address was not 0, then the data is stored in memory at the starting address contained in the header. At the completion of the load the address of the last RAM location used will be moved into the X and Y registers. The SETLFS and SETNAM routines must be used prior to this routine. See KERNAL, Accumulator.

LOAD BASIC Command. The LOAD command copies a program from a mass storage device such as the cassette or disk into the main memory (RAM). The program loaded will erase any program already in main memory but does not alter the program still in mass storage device. The format is:

LOAD"<name>"[,<dev>,<addr>]

<name> is the name of the program to be loaded. On the

disk drive, the drive will attempt to match the name with one already in the directory, and load that particular program. If the symbol * is used in place of a name, the first program on the disk will be loaded. A character followed by * (e.g. B*) will load the first program beginning with B. A question mark can be used for wild card matching (see WILDCARD). When loading from cassette the tape will be advanced until that program is found. On the cassette using a single character (e.g., C) will load the first program on the tape beginning with that character.

<dev> is the device number. For a single disk drive, the device number is 8. For cassette the number is 1. If no device number is entered, the default value is 1.

<addr> is the address. Normally programs are loaded on the Commodore 64 starting at address 2048. If the number 1 is entered here, the program is loaded in the memory space from where it was saved. See Wildcard, Disk, Cassette.

Load Module A file containing object code ready to load into memory.

Load Time The point in the processing of a program when all translation and linking are completed and the program is loaded from disk or tape into memory for execution.

Load—Error Message. This error message from the Commodore 64 that appears when there is a problem with a program on tape.

Loan Amortization* Outputs an amortization chart for any loan or property mortgage. Comm*Data Computer House.

Loan Repayer, The* Reviews the costs of loans and other borrowing before you take the plunge. Disk; printer required. Powerbyte.

LOG BASIC Function. LOG function returns the natural logarithm of <x> (log to the base (e)). The format is:

<variable> = LOG(<x>)

<x> must be a numeric expression which is greater than zero.

Logical File Devices such as a disk drive have a number of types of files on various media. Each file must be opened before data can be sent to it. Files sent to a printer must be treated as if they are being sent to disk. The term logical file describes all these files regardless of the nature of the receiving device.

Logical Operators Logical operators (boolean operators) recognized by the Commodore 64 are AND, OR, and NOT. The result of a logical AND between two bits is 1 if both bits are 1, and 0 if either or both are 0. The result of a logical OR between two bits is 1 if either of the bits is one, and 0 if both bits are 0. The logical NOT operator is performed on only one bit and results in changing a 0 to 1 and 1 to 0. When the logical operators are applied to bytes, the same logic is used one bit at a time over the whole byte.

Logical Screen Line See Line.

Logic-Seeking Some bi-directional printers (such as the Gemini 10X) attempt to make the smallest possible

movement to print the next line. Short lines may be printed either to the left or to the right, whichever is faster. This feature is designed to increase printing speed by minimizing the total travel time of the print head. Often the print head may return at high speed to accomplish this. This feature is known as Logic-seeking.

LOGO* The popular graphics language adapted for the Commodore 64. The package is produced by the original authors of the language. Includes all normal language features plus exclusive Commodore extensions. Commodore.

Long Division* Brush up on your math with this step-by-step, self instructing program. Disk or cassette. Micro-computer Workshops.

Loop BASIC See FOR, NEXT.

Loop Delay Hold Screen Display in BASIC. To freeze the screen briefly while the operator using your program reads a message; write a delay loop after you print the message:

```
1000 FOR Y = 1 TO 2000 1010 NEXT Y
```

To freeze the screen until the operator is done with it, put in a dummy input statement and instruct the operator to press ENTER to proceed. The input variable need not be used in your program:

```
1000 INPUT "Press ENTER to continue";A$
```

Loram The name of a control line that banks an 8K block of memory in and out of the microprocessor's memory. When Loram is high the microprocessor sees 8K of BASIC ROM from address \$A000 to \$BFFF. When it is low the microprocessor sees 8K of RAM in that space.

LRC Longitudinal Redundancy Check. See CRC.

LSB Least Significant Bit.

LSR Logical Shift Right. An Assembly language instruction for the 6510 microprocessor that shifts the bit pattern in the location specified by the argument one bit to the right. The result of the shift is placed in the same location. The right most bit is moved into the carry flag bit and 0 enters from the left to be placed into bit 7. The argument may be A for accumulator or refer to a memory location using zero page, zero page X, absolute, or absolute X addressing modes. The sign bit, zero flag bit, and carry flag bits can be altered by the result of this instruction.

M Codes. ASCII = 77, HEX 4D. CBM ASCII = 77 or 205. m—ASCII = 109, HEX 6D, CBM ASCII = 77. Screen code = 13 or 77. See CBM ASCII.

Ma Bell* Helps you keep track of phone calls, times, and costs. May give you a new outlook on the monthly bill. Disk; printer required. Powerbyte.

Machine Language Program The actual controlling device or "brain" of a computer is the microprocessor. On the Commodore 64 it is the 6510 microprocessor manufactured by Commodore. The device itself is controlled by sending specific numbers (called Machine Code) to the device one at a time. This structured sequence of numbers is called a Machine language program. The microprocessor will only respond to these specific numbers and to utilize the computing power of the Commodore 64 it must receive Machine Code (or object code) instructions.

The Commodore 64 has a BASIC Interpreter built into it which will take BASIC language commands and convert them into object code.

When a BASIC program execution is initiated, the BASIC Interpreter looks at the first line of BASIC statements and converts it into object code (Machine Code). Once the computer has finished responding to that line of object code, the BASIC Interpreter translates the next line of BASIC.

It is also possible to translate the entire BASIC program into object code at one time before running the program. This type of translating program is called a compiler. Running a compiled program is generally much faster than using the BASIC Interpreter. See also BASIC Interpreter, Compiler, Object Code.

MAE* This Macro Assembler Editor word processing program was developed by EHS and has become very popular with assembly programmers. Microtech.

Magazines There are several popular magazines containing useful information about the Commodore 64 and

available compatible hardware and software. Most computer stores and larger bookstores carry a good assortment of these magazines. *BYTE* is an excellent source for general information on microcomputers, although information specifically relevant to the Commodore 64 is buried amid voluminous ads and articles on other machines and general topics. Commodore publishes a magazine specifically about Commodore computers, which will help you keep abreast of the latest application software. Magic Desk* A series of integrated software, animated with pictorial symbols such as a typewriter, a wastebasket, a telephone, a calculator, and a financial journal on a desk. To use a feature of the package, you use the joystick, trackball, or mouse to move a pointing finger to any of the symbolic objects on the screen. Info Designs.

Mailfile* Helps you to develop a listing of names, numbers, and addresses that can be retrieved by various categories. Cassette. Adventures.

Mailing List* Maintains over 1000 records per disk; prints and presorts. Micro Spec.

Mailing List—Home/Business Program* Manages 650 records on each disk; alphabetize and search on various fields. Disk or cassette. Luna Software.

Mailing List, The* Menu-driven programs that can develop complete records of names and addresses, and organize them into small data bases. Other features include alphabetizing, sorting, searching, and printing. Disk or cassette. Galactic Software.

Mailing Lists Computers have become an invaluable tool in the generation of mailing lists. A mailing list is a database, and most database management systems can be tailored to work as mailing lists. Features to consider in choosing a mailing list are its ability to add, delete, and change

information in a mailing list after the list has been started. Some mailing list programs have a fixed format which cannot be altered while others allow the user to create their own fields. Some programs allow the user to sort the list, based on one or more fields, creating an alphabetized list or numerical sequential list. A search option is sometimes available allowing the user to look through the entire list for all entries with a given value. You may want to select only those entries with a particular zip code, or only those entries starting with a particular letter. Be certain that the program selected is compatible with your printer and determine if the printout can be modified and is suitable for your needs.

Mallman, The* Stores names and addresses of business and personal contacts in an organized manner. They can be accessed by different subjects. Disk; printer required. Powerbyte.

Maintenance, Disk File management or disk maintenance are terms which describe keeping track of files on disks. This includes creating them, finding them by name, insuring that adequate free space is available on the disk, maintaining backups and deleting files no longer needed. These functions are supported by the various DOS functions, but require thoughtful planning by the user to insure proper results.

Some data base management (DBM) systems attempt to automate part of the work of keeping track of files and disks. Some DBM systems maintain files of control and tracking data on other files and disks, and may provide alternatives to DOS functions.

Maintenance for the Commodore 64 The computer itself requires no active maintenance beyond keeping it clean and dry. The integrated circuits may be damaged if the vents under the system are blocked. Avoid repeatedly connecting and disconnecting cables if possible, as this will lead to poor connections.

The disk drive also should be well ventilated and out of direct sunlight. The heads within the disk have a tendency to build up oxide deposits from the disks. Periodic use of a commercially available head cleaner will help remove the deposits.

Making an Outline* Make a rough outline of the subtopics in the order in which they appeared in a given article. Review of this article may be as frequent as needed. For elementary students. Cassette. Micro-Ed.

Management Accounting System* The Management Accounting System (MAS-64) is perhaps the most advanced accounting system available for the Commodore 64. It consists of five separate systems which can be purchased individually. They require, in addition to the Commodore 64, a 1541 drive, a 2031 drive, or a 4040 drive. Two 1541 drives or two 2031 drives can be used. They can be configured to produce reports on the 1525 printer, 4022 printer, 8023P, NEC Spinwriter/Diablo, or any properly interfaced printer. They are in menu-driven formats with excellent documentation. Some knowledge of accounting

procedures is necessary, but a video training series and a telephone consulting service are available at some additional cost. The separate systems are:

Accounts Receivable/Billing: Maintains customer billing information. Payments received can be applied by oldest invoice first. Customer files and invoice files are automatically updated at posting. The system can print invoices or credit memos, monthly customer statements, audit trails of all transactions, open item summaries, and summaries of unbilled items. Up to 150 customers, 375 invoices and 40 transactions can reside on one disk.

Accounts Payable: Maintains vendor billing information. Vendor files and invoice files are updated upon posting. Discounts are automatically calculated. The system can automatically print checks as well as vendor activity reports, transaction summaries, open invoice lists, check registers, accounts payable updates and more. Up to 100 vendors, 375 invoices, and 40 transactions can be managed on one disk.

General Ledger: Allows direct posting to the General Ledger. It can be automatically updated when used in conjunction with an accounts payable, accounts receivable, or payroll system. It can produce income statements, balance sheets, lists of transactions, cash receipt, and disbursement journals, as well as a number of other related reports. Up to 300 charts of accounts and 1500 transactions can be maintained on one disk.

Payroll: Maintains a record for each employee including quarterly and yearly totals. It calculates and prints payroll checks with appropriate deductions for federal and state taxes and miscellaneous deductions. It prints reports including W-2s, 941s and payroll journals. It automatically updates general ledger systems when used with that system. Large numbers of employee payroll records can be maintained by assigning separate disks for separate groups.

Inventory Management: Maintains inventory records on stock items. It processes stock receipts, adjustments, and orders. It calculates usage and reorder levels. It prints an inventory summary, reorder reports, shortage reports, stock status reports, price catalog, and sales analysis reports. The system automatically calculates the optimum quantity of an item to purchase based on the cost of ordering versus the cost of holding inventory. The system calculates the number of items to purchase based on how long it takes to obtain the item and the daily usage. Up to 1800 items can be maintained on one disk. Disk; printer required. Info Designs.

Management of Files Disk Maintenance. File management or disk maintenance are terms describing keeping track of files on disks. See Maintenance (Disk).

Mansion* On the estate of a very wealthy tycoon, only the butler knows who stole the loot. It won't be that easy for you to find out. Cassette. Briley Software.

Manual A process done by hand, not automated or programmed.

Manual A reference book, booklet, or other document.

Maps and Globes* A series of programs to be used with the booklet *Skills for Understanding Maps and Globes* by Kenneth Job and Lois Wolf (Follet Publishing Company). Tests the student's knowledge of the geographical world. Micro-Ed.

Mars* You are stranded on a distant planet, and must return home, with or without the help of alien beings. A good beginning game for newcomers to space travel games. Cassette. Aardvark.

Master Grades Program* Assists teachers in keeping track of student grades by keeping track of each student's cumulative score and comparing it to a "possible score" when grades are assigned. Grading scale may be designed by the user. Midwest Software.

Master Library Program* A utility that helps the user keep track of disk files. The system disk comes with a series of program files, each set up for a specific function such as Machine language sorting, printing library, search, and expand library. 700 items may be stored in each file and the system is capable of cataloging up to 8,000 entries through the use of multiple files. A Disk-Abetizer routine is included that alphabetizes a disk and recovers scratched files. Sample libraries are also included with the system disk to demonstrate the operations of the system. Midwest Software.

Master Menu A menu is a screen display which lists a number of possible options and asks the user to select one. When a selection is made by keying in an identifying number or letter (or positioning the cursor beside the desired item, using a light pen, etc.), the selected function is performed. This may require either a branch or subroutine call in the code for the function. The program to carry out this function may also have to be loaded into memory to be executed.

Many application packages use a system of multiple menus. A Master Menu lists the major functions allowed. Selection of an option on the Master Menu causes another menu to display, indicating more detailed options for the selected function. This can be followed by even more detailed menus, and so on. Often completion of a function will cause re-display of the Master Menu. Such a system is called menu-driven.

MasterType* Learn to type before the aliens destroy you. Eighteen levels of learning combine games with education and will have you typing in no time. Disk. Lightning Software.

Matching Capital Letters* Teaches recognition of letters. Press the correct letter on the keyboard that is shown on the screen and race against the computer. For pre-schoolers and kindergartners. Cassette. Micro-Ed.

Matching Small with Capital Letters* Tests recognition of lower case letters as shown on the screen by having the student press the same letter in upper case on the

keyboard. For kindergartners and first graders. Cassette. Micro-Ed.

Media • Memory Map

Media Physical Devices for Recording Information such as programs and data files. The main media for Commodore 64 is disk; however, cassette, RAM, ROM, and other devices are also used. Media are often classified as follows:

- a) removable media, such as disks, cassettes, and some hard disks, or
- b) fixed media, such as most hard disks. Fixed media are not removable from the device that drives them, so there is no ability to store additional data or backup copies off-line (outside the computing system) for insertion when needed. See also Memory.

Media Register* Basic filing program for information storage. Comm*Data Computer House.

Medical Records* Build a medical history for every member of your family. Include immunization records, lists of doctors, medications, etc. Powerbyte.

MEMBOT The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FF9C, MEMBOT can either read or set the bottom of memory. If the accumulator carry bit is 1 when this routine is used the contents of the start of RAM Pointer is returned into the X and Y registers. If the accumulator carry bit is 0 when this routine is called the contents of the X and Y register are moved into the start of RAM Pointer. See KERNAL.

Memory Any device which can store information for retrieval when needed. The Commodore 64 relies primarily on Random Access Memory (RAM), Read-Only Memory (ROM), disks, and cassettes. The term Memory, by itself, is usually a reference to RAM, the general purpose, erasable and reusable memory.

ROM contains fixed data, usually programs like the Commodore 64's BASIC ROMs and its ROM KERNAL. The KERNAL contains the fundamental Machine language programs to run the devices such as the monitor, printer, disk drive, and cassettes, which are attached to the Commodore 64. ROM and RAM together make up the internal or main memory of the computer.

External memory, such as cassettes and disks, require mechanical motion to retrieve data so they are hundreds or thousands of times slower. Data in internal memory is immediately available to programs for processing. Data in external memory must be copied into internal memory (GET or INPUT#), processed, then copied back out to external memory (PRINT#).

If data has been created, it can be written out to external memory without an INPUT first. And, if data read in from external memory has not been modified, there is no need to write it back out since the original copy is still there.

While external memory is slower than internal memory, it does have advantages. It is much cheaper per character of data stored on-line (available for processing without manual intervention). Storing external memory data off-line

(on disks or cassettes) allows essentially unlimited storage of data. Of course this requires a manual step of inserting the disk or cassette before the data can be loaded into the internal memory for processing. See also Virtual Memory, Memory Map, Bubble Memory.

Memory Address A number or variable designating a location in memory. See Address.

Memory Card A card containing RAM or ROM memory to expand or enhance the computer's main memory.

Memory—Amount Free BASIC command. See FRE.

Memory—Change with BASIC See POKE.

Memory—Computer Storage in Bytes. Byte is a label for storage that holds one character (letter, digit, etc) in computer memory or disk. Abbreviated B or (in thousands) KB or simply K (actually, 1K = 1024 bytes because this is an even power of 2). Commodore 64 has 64K (or 64KB) of internal memory, or to be precise 65,536 bytes. See Memory Management.

Memory Execute Disk Command. The memory execute command given through the command channel will begin executing any Machine Code instructions in ROM or RAM of disk drive beginning at the address specified. The format is:

```
OPEN15,8,15  
PRINT#15,"M-E:"CHR$(LS)CHR$(MS)
```

(LS) is a decimal number for the least significant part of address. LS = Decimal Address MS + 256.

(MS) is the decimal number for most significant part of address. MS = INT(decimal address/256)

Memory Management The internal memory of the Commodore 64 consists of 64K RAM and 20K ROM (Operating System and BASIC Interpreter). Since there are 16 address lines, only 64K addresses are possible at any given time. The Commodore 64 manages this memory scheme by banking blocks of ROM in and out of the configuration. Control of this operation is maintained at address \$0000. As an example, the 8K of BASIC memory ROM can be found at address \$A000-\$BFFF when bit 0 of address \$0000 is set to 1. When that bit is set to 0, 8K of RAM are seen at that address \$A000-\$BFFF.

Similarly, 8K of KERNAL ROM can be banked in and out of the picture as well as 4K of input/output registers. When first powered on, the Commodore 64 sets address \$0000 in such a way that the system sees 8K of BASIC, 8K of KERNAL and 4K of I/O registers.

Memory Map A memory map consists of a table of addresses (locations in memory) and corresponding functions of those addresses. Often the hardware of a computer is controlled by a specific memory location. Changing the value in that location will change the settings in the hardware. An address may be specified for an I/O function, it may contain ROM data, or it may be a free program to enter data. For example, the location 53281 controls the color of the screen. POKEing appropriate

numbers into that address will change the color of the screen.

Memory Segment A continuous block of memory addresses, such as 0 to 16K.

Memory-Read Byte from BASIC. See PEEK.

Memory-Read Disk Command. This command through the command channel enables you to read any address in the 16K ROM or 2K RAM within the 1541 Disk Drive. The command itself locates the specific address. The data at that address can be obtained with a GET statement through the error channel. The format is:

```
OPEN 15,8,15
PRINT#15,"M-R:"CHR$(LS)CHR$(MS)
GET#15,A$
```

The address is expressed in decimal and can be computed as follows:

(LS) = decimal address - MS * 256;

LS is the decimal number for the least significant part of the address.

(MS) - the high byte = INT (decimal address / 256);

MS = decimal number for the most significant part of the address.

Memory-Write Disk Command. The Memory Write command enables you to write into the RAM within the 1541 Disc Drive. The command specifies a starting address for the data to be entered and is followed by the data. Up to 34 bytes of data can be written in one command. The format is:

```
OPEN 15,8,15,"M-W:"CHR$(LS)CHR$(MS);CHR$(n);CHR$(d)
(LS) is the decimal number for the least significant part of the address (LS=Decimal Address-MS*256).
```

(MS) is the decimal number for the most significant part of the address (MS=Decimal Address/256).

(n) is the number of characters in data to follow.

(d) is the decimal number for the Machine Code of data.

MEMTOP The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FF99, MEMTOP either reads or sets the top of RAM. If the carry bit of the accumulator is set, the top of RAM pointer is returned into the X and Y registers. If the carry bit of the accumulator is 0, then the contents of the X and Y register are moved into the top RAM pointer. See KERNAL.

Menu Screen display which lists a number of possible options and asks the user to select one. When a selection is made by keying in an identifying number or letter, positioning the cursor beside the desired item, using a light pen, etc., the selected function is performed. This may require either a branch or subroutine call to the code for the function, or the program to carry out this function may be loaded into memory and executed.

Many application packages use a system of multiple menus. A Master Menu lists the major functions allowed. Selection of an option on the Master Menu causes another

menu to be displayed, indicating more detailed options for the selected function. This can be followed by even more detailed menus, and so on. Often completion of a function will cause re-display of the master menu. Such a system is called menu driven.

Menu Driven See Menu.

Message A statement or code printed out or displayed on the screen by a program to let you know what is happening. Examples include prompts when the program expects you to input something, error messages which tell you something about what went wrong, and informational messages such as "Copy Complete".

Meta Music I* Compose music and learn the basic elements of musical theory. Teach yourself rhythm, tempo, harmony, melody, and more. Disk. Commodore.

Meteor* You control a starship trapped in a meteor shower. Avoid the metors or destroy them with your laser. Includes sound and full-color, high-resolution graphics. Cassette. Star Tech, Inc.

Metric-Calc* A metric conversion system including area, distance, temperature, and weight. Disk or cassette. Micro Software Systems.

M'File* A menu driven data management program. The number of fields and their length is determined by the user, up to 32 fields per record and 78 characters per field. A record can contain up to 250 characters. Fields within a record can contain words, numbers, or formulas with addition, subtraction, multiplication, division, inequalities such as < or ≠, and IF THEN statements. There are 10 user-defined interfield formulas, but formulas can reference any other field. Records can be sorted on any field in ascending or descending order. Searches can be performed on any or all fields with a special high speed "keyfield" search. Fields can be added to a record (as long as the maximum number of characters does not exceed 250) after a record has been established. Data can be output in user-defined formats, giving great flexibility in outputs, with escape sequences able to set different options on printers. One menu option allows M'File to be merged into major word processor programs available. The quality of the program is matched by the documentation. It is clear, concise, and comprehensive. M'File is by M'Soft, a product of Double E Electronics, Inc.

Microbuffer In-Line* Computer Peripheral. A printer buffer that may be used with the Commodore 64 and any printer or modem. Both parallel and serial versions are available. The memory can be upgraded from a minimum of 32K to 256K bytes by using expansion modules. Practical Peripherals, Inc.

Microprocessor An integrated circuit that is essentially the "brain" of the computer. It is responsible for fetching

MID\$ • More Suffixes

and executing each instruction from a program. It performs the routine arithmetic and logical operations on data. In the Commodore 64, the 6510 Chip is the microprocessor. The chip itself has forty pins that include sixteen address lines for an addressable memory range of 64K bytes and eight bi-directional data lines. The chip is capable of executing fifty-six different Machine Coded instructions and performing both binary and decimal arithmetic. See Machine Language Program.

MID\$ BASIC Function and Statement. When used as a function, MID\$ returns the requested part of a given string. The format is:

<stringvariable> = MID\$(<X\$>,<n>,<m>)

<X\$> is any string expression.

<n> is an integer expression in the range 0 to 255.

<m> is an integer expression in the range 0 to 255.

The MID\$ function returns a string of length <m> characters from <x\$> starting with the <n>th character. If you leave out <m> or if there are fewer than <m> characters to the right of the <n>th character, all rightmost characters beginning with the (n)th character are returned. If <m> is equal to zero, or if <n> is greater than LEN(X\$), then MID\$ returns a null string.

When used as a statement, MID\$ replaces a portion of one string with another string. The format for the statement form is:

MID\$(<X\$>,<n>,<m>)=<string variable>

Mini Jini* Database management system for the Commodore 64. The program is capable of storing 750 characters per record. MOB Moveable Object Blocks. See Sprites.

Modem MOdulator DEModulator. A device to convert the digital voltage level signals of the computer to modulated (frequency or tune) signals for transmission over phone lines. Required at both ends of a phone line for telecommunications. See also Vicmodem.

Modem Interface* Lets you connect almost any direct connect or acoustical modem to your system. It is compatible with the CAT, Microconnection, or DC Hayes modems. Bytesize Micro Technology.

Modulator, RF A computer is designed to connect directly to a monitor. To connect a computer to a television set you need an RF Modulator. It makes necessary corrections on the generated signals. The Commodore 64 comes with a modulator and can be connected directly to any black and white or color TV. Although there is a switch on the module cable to disengage the TV, occasionally the Commodore 64 video display is subject to interference. Moving the computer or TV often eliminates this problem. Extending the cable and wrapping the leads of the cable around a ferrite may solve the problem. There is also an audio/video port to connect directly to a monitor. See Monitor—Video.

Monitor—Program See Assembly.

Monitor—Software A monitor program gives the user direct access to computer memory locations. A good monitor will not only let the user enter and retrieve bytes from specific locations but will let him load and save programs to and from locations specified by the user. Monitors also allow the user to check the contents of the key registers (such as the accumulator) and alter data in those registers. A monitor is often used to debug Machine language programs by allowing the user to locate errors in a program and make specific changes.

Monitor—Video A cathode ray tube which receives signals by cable. A television set receives high frequency radio signals. An RF modulator is used to connect with the computer corrects the signals. A monitor can be connected directly to the computer. A monitor has better resolution with less interference but may not have a built-in speaker. The Commodore 64 has an audio video port in the back to connect to a monitor, and an RF modulator to connect to a T.V.

Monitor Link* Cable assembly that connects your computer to a monitor. Also lets you connect your computer to your stereo for great audio reproduction. Micro Systems Development, Inc.

Moving the Cursor Blinking square that appears on the screen when powered up and during most programs. Pressing a key on the keyboard enters the character on the screen and moves the cursor one square to the right. At the end of the line the cursor automatically returns to the left and moves down one line. Keying in a carriage return (RETURN) will also return the cursor to the left and essentially enter a blank space, erasing any character in the cursor path. The cursor can be moved without affecting data using the CRSR up, down, left, and right keys on the lower right of the keyboard. The cursor can be moved left and used to delete characters using the INST/DEL key. The cursor can be immediately returned to the upper left corner hitting the CLR/HOME key.

MPU Micro Processor Unit. The actual chip containing the processor.

M-R See Memory Read.

Multi-Color* Multi-color, high resolution character editor with the following features: auxiliary and screen color commands, 8 power magnification, cursor controls, Saves and Loads set to all input and output devices. Just Another Software Co.

Multi-Color Character Mode The Commodore 64 has two possible screen formats: hi-resolution mode or character mode. In character mode the screen is divided into 1000 squares (40 columns by 25 lines). In standard character

mode each character must be one of sixteen colors. Multi-color character mode allows four different colors for each character. The multi-color character mode is enabled by setting bit 4 of address 53270. The four colors are established using address 53281 to 53283. Multi-color character mode sacrifices some resolution since colors are set in pairs of pixels.

Multilanche* Solve problems correctly to avoid being smashed by falling objects. Cassette. Comm*Data Computer House.

The function and control keys are used to change the musical settings and special effects such as waveform, octave, and percussion (rhythm select), and will also adjust the pitch to accompanying instruments. Commodore.

Musicom* Allows the user to compose for three different instruments at the same time. Accents, pitch, and timbre are adjustable. Musicom also presents printed lyrics. Computer Alliance.

N See NEW. Disk Command.

Names The rules governing variable names in BASIC for the Commodore 64 are:

- a) must start with a letter;
- b) can be any length, but only the first two characters are used;
- c) cannot use any keywords, including any BASIC command or the variables TI, ST or TI\$. See Reserved Words;
- d) end with a type declaration:

\$ for String variables

% for Integer variables

no type declaration means Floating Point to the program.

NEW BASIC Command. Deletes the program currently in computer memory and clears all variables. The format is:

NEW

It is used to clear the memory of any previous statements or variables before entering a new program. If the NEW command is not used you will end up with an unusable combination of lines from your old and new programs.

NEW—Disk Command. When sent through the command channel, the NEW command erases the entire disk, puts timing and block markers on the disk, and creates the directory and BAM. The format is:

OPEN15,8,15 PRINT#15,"NEW0:<name>,<ID>"

<name>is arbitrary, assigned by the user.

<ID>is an arbitrary identification made by the user consisting of two characters. <ID> is placed on directory and all blocks on disk.

Next End of FOR...NEXT loop in BASIC. See FOR...NEXT.

Next Without For This is an error message that appears on the Commodore 64 when a variable with the NEXT statement doesn't correspond to the variable in the FOR statement.

Nibble Half a byte or 4 bits.

NMI See Interrupt Machine Code.

No Block An error message from the 1541 disk drive incurred when you try to use the BLOCK-ALLOCATE command on a block that is already in use. The error channel #15 returns this message as well as the track and sector of the next available block.

No Channel An error message from the 1541 disk drive incurred when a user tries to open more than five sequential files or six direct access channels simultaneously.

Noise Interference on a system communications line or random unknown signals.

Non-Destructive Read-Out The memory contents are not erased or displaced when other data is read.

Non-Encoded Keyboard See Keyboard.

NOP • Numeric Variables

NOP or NOOP NO OPeration. An Assembly language instruction for the 6510 microprocessor that does nothing for 2 cycles. It can be used in a delay loop but does not affect any flag or any registers.

NOR Condition of being Not-OR.

Normal Size Print To return to normal 10-character-per-inch print size, you must turn off all non-standard print options.

NOT Negative operation which changes every 1 in a byte to a 0 and every 0 in a byte to a 1. In many languages it is also used as a logical operator to reverse the outcome of a conditional test.

NOT-AND Logical Operator A NOT-AND B is a synonym for NOT (A AND B).

Not Input File This is an error message from the Commodore 64 encountered when a program attempts to INPUT or GET data from a file that was specifically opened as an output file.

Notch, Write-Protection A disk is write-protected if it does not have a notch about one inch down on the right side. The notch may be absent or covered with an adhesive tab, in which case it is mechanically impossible to write to the disk. The disk can still be read and files loaded from the disk to the computer. Attempting to write to a protected disk will give a WRITE-PROTECTION ON error.

It is a good idea to put an adhesive tab over the notch of any disk containing important data or programs, particularly prior to using Backup. If you inadvertently mix the original and backup copy, no data will be lost.

For more details on the series, see also Inside BASIC. Sim Computer Products, Inc.

Numeric Data Numeric variables and constants are numbers that are either integers or floating point. These numbers can be added, subtracted, multiplied, divided, compared, etc. Numeric variables have a % symbol following the variable for integers and no symbol for floating point. String data have a \$ symbol following a variable or have constants in quotation marks. String data can also be comprised of numbers, but the computer sees them only as symbols and cannot perform arithmetic operations on them. The expressions A=27 and A\$="27" are viewed by the computer as two completely different expressions.

Numeric Value of String BASIC. See VAL.

Numeric Variables Floating point. A variable is assumed to be floating point if it does not have the symbol % (for integer) or \$ (for string) following the variable. Floating point variables can be positive or negative and are assumed positive if there is no "-" symbol before it. A floating point may include a decimal point. If it doesn't have one, it is assumed to be at the far right of the number.

O Codes. ASCII = 79, CBM ASCII = 79 or 207, HEX = 4F. o—ASCII = 111, HEX = 6F, CBM ASCII = 79. Screen code = 15 or 79. See CBM ASCII.

O Stands for Output or Overflow.

Object Code The code produced by a compiler or an assembler program. Generally represented by hexadecimal numbers, each number representing a particular operation of the microprocessor. It is in fact the only code that can be directly executed by the computer.

Object Program A program written in Machine language. Most programs are written first in a higher-level language such as BASIC. This program is referred to as a source program. A microprocessor such as the 6510 in the Commodore 64 does not recognize BASIC words, so they must be translated into a Machine language program. This translated version, ready to be executed by the microprocessor, is called the object program. The process of translating is called compiling. BASIC programs are usually interpreted, which means the instructions in the source program are used by a BASIC interpreter to control a series of subroutine calls. In this case no permanent object program is produced. See also BASIC Interpreter, BASIC Compiler.

Odd Parity The parity bit is added to a word so that the total number of "1" bits becomes odd. Even parity means the total number of "1" bits becomes even.

Off-Line A device or media that is outside of or disconnected from the computer system is off-line. On-line means that a device or medium is inside of or connected to the system.

A disk is on-line when it is in a working disk drive. A printer is on-line if it is attached, powered on, and ready to print. The printer is off-line if it is disconnected, powered off, or switched to its "off-line" state by an on-line/off-line switch. See Memory.

Offset Address The smaller part of a base register offset/pair. The data to be processed is located at (effective address)=(contents of base register)×(offset).

Oil Well* Pretend you're an oil barron by reducing numbers to their prime factors and increasing your chances for a gusher. For elementary students. Cassette. Micro-Ed.

Omega Race* Command a starship and control an arsenal of weapons as you travel throughout the galaxy in search of adventure. Commodore.

On the Line* Learn about mixed numbers and improper fractions while coaching a game of football. For elementary students. Cassette. MicroEd.

One Line Multiple BASIC Statements. You can put a colon (;) at the end of a statement and enter another statement on the same line without giving a new line number. A maximum of 80 characters may be used in the form of multiple statements on one line. The line number at left refers to all statements on the line.

ON...GOSUB and ON...GOTO BASIC Statements. ON...GOSUB and ON...GOTO are used to branch to one of several specified line numbers, depending on the value of an expression. The formats are:

ON <n> GOTO <line>[,<line>...]

ON <n> GOSUB (line)[,<line>...]

<n> is a numeric expression which is rounded to an integer, if necessary. It must be in the range 0 to 255.

<line> is the number of a line you wish to branch to.

The value of <n> determines which line number in the list will be used for branching. If the value is 4, the fourth line number in the list will be the destination of the branch.

In the ON...GOSUB statement, each line number in the list must be the first line number of a subroutine. This means that at some time it will be necessary to have a RETURN statement to bring you back to the line following the ON...GOSUB.

If the value of <n> is zero or greater than the number of items in the list (but less than or equal to 255), BASIC will continue with the next executable statement.

On-Line A device or medium inside or connected to the computer system is on-line. Off-line means that a device or media is outside of or disconnected from the computer system.

A disk is off-line when it is in a box, and on-line when it is in a working disk drive. A printer is on-line if it is attached, powered on, and ready to print. The printer is off-line if it is disconnected, powered off, or switched to its "off-line" state by an on-line/off-line switch. See Memory.

OPEN BASIC Command. Establishes a channel through which data can be sent and received from a peripheral device. It is essentially the command that makes the connection with a peripheral such as a cassette, disk, modem, or printer. Once a channel has been opened with a

device, the commands PRINT#, GET#, and INPUT# can be used to send and receive data to and from the device. The format is:

```
OPEN <lfn>,<dev#>,<add#>, [“<fname>,<type>,<mode>”]
```

<lfn> is the logical file number that is used to reference PRINT#, GET# and INPUT# commands so data is sent to the right channel.

<dev#> is the device number of the peripheral to which data will be sent. For a single disk drive, device number 8 is used; for a printer on the serial port, device number 4 is used. If the device number is left out, the computer will assume device number 1 (which is cassette).

<add#> is the secondary address has different meanings depending on the device you are opening. In disk files <add#> may be 2-14 and refer to channel numbers set by the user. For a cassette, a number 1 opens the cassette for writing, and a 2 places an end of tape marker when the file is closed. In the VIC 1525 printer, a 7 will tell the printer that the upper and lower case letters are to be printed.

<fname> is the file name up to 16 characters. This is optional for printers or cassette.

<type> is used in disk files—either “S” for sequential, “R” for relative or “P” for program.

<mode> is used to distinguish between a sequential read (R) or sequential write (W). In opening an RS-232 channel, a slightly different format is used. See RS-232 for the Commodore 64.

Open Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFCO, OPEN will open a logical file that has been set up using the SEFLFS and SETNAM routines. See KERNAL.

Operand Operations are performed upon entities called the operands. For example, the statement LET A=B+C specifies that the operation of addition is to be performed on the operands B and C.

Operating System The software and hardware responsible for organizing the memory of a computer and orchestrating its activities. It is built into the ROM of the Commodore 64, and contains the BASIC Interpreter, the KERNAL, and the Screen Editor.

Operating System Utilities* See Commodore 64 DOS Wedge; PET Emulator; Smart 64 Terminal, The; Terminal Pak Series.

Operation Action of a program resulting in a defined instruction being executed.

Operation Code Part of the Assembly or Machine language program which specifies what operation is to be performed.

Operator Symbols within a program such as * (for multiply), - (for subtract), or + (for add), which specify what operation is to be performed.

Operator—User Person using a program. You will often be the only user of programs you write, but if others will use your program, you need to make it user friendly. Give clear prompts for every item of input data, freeze the screen long enough for them to read or act on the information displayed, provide clear error messages if anything is entered incorrectly or error situations arise. This is often referred to as “human engineering”—making the program easy to use as well as technically correct. “

There are several other guidelines for writing user friendly programs. If a complex series of data items has been typed in but some entries turn out to be invalid, the user should be able to re-enter only the bad items. Error messages should indicate not only that an entry is invalid, but how it is invalid and, if at all possible, some hints as to how to correct it (such as a list of possible correct values).

Optimization Changing either the software or the hardware of a computer system so that it operates faster or more efficiently.

Options Choose from Menu. A menu is a screen display which lists a number of possible options and asks the user to select one. When a selection is made by keying in an identifying number or letter, positioning the cursor beside the desired item, using a light pen, etc., the selected function is performed. This may require either a branch or subroutine call to the code for the function, or the program to carry out this function may be loaded into memory and executed.

OR BASIC Logical Operator. A logical operation performed between two numbers. The result of a logical OR between two bits is 1 if either of the bits is 1. The result is 0 if both bits are 0. When the logical OR is performed between two bytes, each pair of corresponding bits is ORed to yield a resulting byte. For example, if the binary number 10001001 is ORed with 10010001 the result is 10011001. The logical OR is often used to set a single bit in a byte without altering any of the other bits. ORing the first number with 01000000 will result in 11001001. The format is:

```
<operand> OR <operand>
```

An example is:

```
20 IF A$="Y" OR B=3 THEN GOTO 100
```

OR OverRun. The status flag of the Universal Synchronous/Asynchronous Receiver/Transmitter (UART) goes to 1 if a new character is written on top of an old one.

ORA OR with Accumulator. An Assembly language instruction for the 6510 micro processor that performs the logical OR function with the accumulator and data in the argument. The result of the logical OR is placed into the accumulator. The addressing mode of the argument may be immediate, zero page, zero page X, absolute, absolute X, absolute Y, (indirect X), and (indirect Y). The sign flag bit and the zero flag bit can be altered by the result.

Order Entry Software See Order Tracker.

Order Tracker* Deals with customers and their purchase orders to help clarify your business operation and give easy access to important data. Disk; printer required. Powerbyte.

OS Stands for Operating System.

Out of Data This is an error message from the Commodore 64 encountered when a program READING from a DATA statement runs out of data. Remember to separate data properly in a DATA statement and make sure there is a one-to-one correspondence between the number of READs and the amount of data.

Out of Memory This is an error message from the Commodore 64 indicating that there is no more RAM memory available. It also occurs when too many FOR loops are used or when there are too many GOSUBs used. Remember that arrays which take up one program line often occupy a lot of RAM.

Output Information coming out of a program. It may be going to a screen, printer, disk, speaker, etc.

OV OVerflow. When the number of digits that result from a mathematical operation exceeds the number of registers available to hold them, this is called overflow.

Overflow An error message indicating that a value computed has exceeded the maximum value allowable on the Commodore 64 (1.70141884E+38).

Overflow When performing arithmetic operations in Machine language, if the results involve the movement of a "1" in bit 6 to bit 7, the Overflow Status Flag is set.

Overflow Flag Bit See Status Register.

Overflow In Record Print# An error message in the 1541 disk drive incurred when more than the defined or allowable number of characters is PRINT#ed to the drive. Remember, the carriage return is included in the characters sent.

Overlay Different routines within a program which occupy the same memory location. They are loaded as needed during the operation of a program. Conflict can occur if two routines with different overlays try to use the same location at the same time.

Over-Run Error The previous character in a register hasn't been completely read when a new character is loaded into the register.

Over-Striking The printer returns to a position where a previous character was struck and strikes a new character on top of it, producing a combination character. Also called boldfacing.

Over-Voltage Protection The computer's circuitry is protected from undesirable increases in the AC power line voltage.

P Codes. ASCII = 80, CBM ASCII = 80 or 208, HEX = 50. p—ASCII = 112, CBM ASCII = 80, HEX = 70. Screen code = 16 or 80. See CBM ASCII.

P See Parity, POSITION.

Package Software. A software package is a group of computer programs, including data files and documentation, that perform a function or group of related functions on the computer. These are called applications software when the programs are devoted to an end user task. Examples are a word processing package, an accounting package, etc. They are called systems software packages when they aid in the use of machinery, such as a data base management package, a disk operating system, or a program development package.

Packed Decimal Two or more binary coded decimal digits are present in every byte. The ten decimal digits 0 through 9 are stored in a 4-bit representation. 1 is coded as 0001, 9 as 1001, etc.

Packet A short set of data of a predetermined length that fits into a particular location. The set is then transferred in a network of devices.

Pad The rectangular base where the wire of a computer chip is connected.

Page Length The number of lines that can be printed onto a sheet of paper. On a standard sheet, 66 lines of data can be typed using a standard 1/6-inch line format.

Pagination Automatic page numbering performed by some word processor programs.

Paging To switch from one full screen of information to another, especially in a word processing program; you can page either backward or forward. In memory, a page is a logical set of storage used for the management of memory; in a paging system, the memory location is designated by a page number or address and an address within the page.

Pail Green* Learn about fractions while you accumulate money from the well. Recommended for elementary grades. Cassette. Micro-Ed.

Panorama, 64* A graphics utility package that lets you create high-resolution graphics on the screen and dump onto the VIC 1525 printer. Use joysticks to control the 64000 pixels on the screen in the hi-res mode to draw straight or curvy lines and create background patterns. Uses the full graphic features of the Commodore 64. Comes with a library of 19 digitized pictures to illustrate the graphics capability of the C 64 and the drawing power of the 64 Panorama. Cassette. Midwest Micro Associates.

Parallel Simultaneous handling of processes, transmissions, or data storage. In most microcomputers, parallel I/O connections have 8 wires to carry 8 bits of a byte simultaneously (or in parallel). This is in contrast with a serial interface, where only one data wire is available. The 8 bits of a byte are transmitted one after another (or serially). The I/O device must collect all 8 bits for each byte.

Parallel Cable* Interface cable. Parallel Cable is an interface cable designed to hook up any Centronics-type printer to the Commodore 64. The package includes driver programs which, when executed by a SYS argument in a BASIC program, will send the output (or program listing) to the printer. The driver programs are Machine language subroutines that are POKEd into the Computer's RAM memory outside of the BASIC program area. Microware Distributors, Inc.

Parameter A definable variable in a program or system which can be used to send information to and from a subroutine or procedure. A parameter may take on various values which are used in subsequent processing by a program.

Paratrooper* You are in charge of a squadron of helicopters that must drop their load of skyjumpers behind enemy lines. In this fast-paced military games high-resolution graphics and sound add to the excitement. ComputerMat.

Parity Error detection technique that uses a one-bit indicator at the end of a word. Odd parity sets the parity bit to make the total number of bits odd. Even parity sets the parity bit to make the total number of bits even.

Parser A routine that analyzes a program instruction to set up its tree structure according to the programming language's syntax.

Parting Shots* Remove a random number of items from each of nine squares and convert what remains into fractions. For elementary students. Cassette. Micro-Ed.

Parts of Speech* Students must identify the highlighted sections of sentences. Cassette. Comm*Data Computer House.

Pascal A structured computer language descended from ALGOL 60. It has new features, such as "records" (data structure definition) and "sets." It has a well-defined

standard—the Report portion of the book, *Pascal: User Manual and Report* by Kathleen Jensen and Niklaus Wirth. It is a language suitable for a wide variety of chores, from systems to application programming. It is designed so relatively naive readers and those other than the original programmer understand the functioning of a Pascal program.

Structured languages represent a major improvement for programmers who want to predict the behavior of a program. It is much easier to understand the function of an IF...THEN...ELSE structure in Pascal than to trace GOTOs and statement labels to remote, unpredictable places. Some of the dialects of Pascal implement all the structures necessary to eliminate GOTOs. It allows for more complete structuring than FORTRAN 77 or the (semi) structured dialects of COBOL.

Pascal is strongly typed. The “type” (floating point, integer, set, record) of a variable is traced even through procedure calls, where a language like FORTRAN only checks the type through the current local routine. This helps to point out a major class of programming errors. Pascal, like other recent languages, requires the explicit definition of all variables as a guard against introducing a misspelled variable. This is otherwise difficult to spot.

The Pascal standard includes an input/output package (this is important for a language intended to be used in textbooks), but fixes the possible style of I/O.

Pointers and records give the high-level language programmer access to powerful techniques for handling complicated data structures, like linked lists and trees, formerly only available to assembly language programmers. In a language like FORTRAN these structures must be “simulated” inside an array with the structure only diagrammed in documentation or the inside of the programmer’s head.

The p-System is an operating system written primarily in Pascal. The P-System is available on a wide range of computers, making programs written in Pascal more portable. See UCSD p-System and Pascal MT+.

Pascal MT+ This is a version of the Pascal programming language marketed by Digital Research, the company that brings you CP/M. It was originally developed for 8-bit computers and now works in a 16-bit environment under CP/M-86 or Concurrent CP/M. Pascal is a structured programming language developed by Niklaus Wirth in the late 60s. Although Pascal was originally developed as a teaching language, it has become popular with computer professionals as well as beginners.

Recent versions of Pascal MT+ have been enhanced with a Speed Programming Package, which adds a full-screen editor and a syntax checking program. Many simple errors can be identified and corrected before running the compiler, saving you time and effort.

Pascal MT+ includes many useful extensions to the original language definition. Byte, word, and string data types have been added along with procedures to manipulate them. Dynamic array handling and the ability to include in-line Assembly language have also been added. A modular

compilation system is useful for assembling large programs with separately compiled modules.

The documentation does not try to teach you Pascal, but assumes that you will use other reference and tutorial books to learn the language. It covers differences between Pascal MT+ and other version of Pascal, as well as operational instructions on how to use Pascal MT+. Digital Research, Inc.

Pass Make information from one process or program available to another process or program. Similar to a football pass, except that one or more bytes of data replaces the football. Also, the receiver is a program. The sender may be a program or a person typing the data onto a command line to be “passed” to a program. The two most common examples would be DOS passing parameters from the command line to a program (see Relocating Loader) and a BASIC program passing variables to a subroutine.

Password Used for identification and security purposes on a computer system. Each user is assigned a specific set of alphanumeric characters to gain entrance to all or part of the computer system.

Patch For debugging or alteration of a software program, a section of code is inserted into the program which changes its control functions.

Pause For Operator to Read or Respond to Message. To freeze the screen briefly while the operator using the program reads a message. A delay loop using a FOR...NEXT statement may be used. For example:

```
1000 FOR Y = 1 TO 2000 : 1010 NEXT Y
```

To freeze the screen until the operator is done with it, a dummy input statement is used. It instructs the operator to press ENTER to proceed. The input variable need not be used in the program. For example:

```
1000 INPUT "Press ENTER to continue";A$
```

PLOT The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFF0, PLOT will locate the cursor in X Y coordinates (0-79 for X, 0-24 for Y) into the X and Y register. If the carry bit of the accumulator is 0 then the cursor is moved to the position determined by the X and Y register. See KERNAL.

Plotter A computer controlled mechanical device which draws images upon a screen or printer.

PLP Pull Processor status from stack. An Assembly language instruction for the 6510 microprocessor that POPs the top word of the stack and places it into the status register. The stack pointer is incremented and the sign flag bit and zero flag bit can be altered by the POPped word.

Plug-Compatible Devices or components which use the same plugs and therefore can be used interchangeably without modification within the computer system.

Pointer A data item whose contents is the address of another data item.

POKE BASIC Statement. The user may enter specific values or data into a particular memory location. POKE places a byte into a memory location. The format is:
POKE <n>,<m>

<n> must be in the range 0 to 65535. It indicates the address of the memory location where the data is to be written.

<m> is the data to be written to the specified location. It must be in the range 0 to 255.

The complementary function to POKE is PEEK. POKE and PEEK are useful for efficiently storing data, loading Machine language programs, and passing arguments and results to and from Machine language subroutines. BASIC does no address checking, so use caution when assigning address locations. You don't want to POKE data in BASIC's stack, BASIC's variable area, or your BASIC program.

Polling Inquiring about the status of each device according to a schedule.

POP A programming instruction where the last word is removed from the top of a stack.

Port A physical I/O connection. An address providing a connection between the computer's internal processor and an external device. Ports are used to attach input and output devices.

POS BASIC Function. Returns the present location of the cursor. Since the screen display line is 40 characters, the numbers 40 through 79 refer to the second screen line. The format is:

POS(<var>)

<var> is a dummy variable (let it be 0).

POSITION Disk Command. The POSITION command, when sent through the command channel, locates a specific record of a relative file. There can be up to 720 records in a relative file and before data can be sent between disk and buffer the specific record must be identified. Used in relative files, the format is:

OPEN 15,8,15

PRINT #15,"P"CHR\$(<channel>)CHR\$(<recordlow>)
CHR\$(<recordhigh>)CHR\$(<position>)

<channel> 2-14 must be previously opened by the user. data will be moved to and from disks through it.

<recordlow> is the least significant part of the address of the record within the relative file. Since there are 720 possible records, two bytes are required to specify a location.

<recordhigh> is the most significant part of the address of the record within the relative file.

<position> is the byte within the record from 0 to the maximum specified in the open statement.

Positive Logic Voltage level "most positive" in the computer system is the true level; the false level is the voltage level closest to zero.

The system package comes with an easy-to-follow manual that includes a tutorial for creating and manipulating records, and a glossary to familiarize the user with the terms used in database systems. The main program is menu-driven and it uses the special Commodore function keys to access the options. Uses random files to store and retrieve records. Each record may have up to twenty fields and each field may contain up to seventy-nine characters. The maximum size of each record is 254 characters. In the Direct File Maintenance mode of the program, the user may Add, Change, Delete, Browse, and Copy records. The Report Writer program allows creation of user-formatted hardcopy of the records in a specific file. A special program is available for generating mailing labels. For printing reports, records may be selected by specified fields. Pattern matching is available for each field for searching for specified character strings. The manual includes a section on the advanced features of Powerfile such as file calculations, restructuring, creating sequential files, and linking the Powerfile to other software. PRINT BASIC Statement. Displays data on the screen. The format is:

PRINT <list of expressions>[:] or ?<list of expressions>[:]

<list of expressions> is a list of numeric and/or string expressions, separated by commas, blanks, or semicolons. You must enclose any string constants in the list in quotation marks.

A PRINT statement alone will display a blank line. The question mark (?) may be used as shorthand for PRINT.

The punctuation in the <list of expressions> determines the spacing of the printed items. BASIC divides the screen line into zones of 10 spaces each. In the <list of expressions>, a comma will cause the next item to be printed starting in the first space of the next zone. A semicolon (;) causes the next value to be printed immediately after the last value. Placing one or more spaces between expressions is the same as typing a semicolon between them.

If a comma, semicolon, SPC, or TAB function ends the list of expressions, the following PRINT statement begins printing on the same line, spacing accordingly. If the list of expressions ends without a comma, semicolon, SPC, or TAB function, a carriage return is performed at the end of the line and the cursor is moved to the beginning of the next line.

PRINT# • Program

If the length of the value to be printed is more than the number of character positions remaining on the current line, then the value will be printed at the beginning of the next line.

Printed numbers are followed by a space. Positive numbers have a space in front of them and negative numbers have a minus sign in front of them.

PRINT# BASIC. Used to write data to previously opened files. The number with the PRINT# command is used to reference that file. Information being written to a file needs some sort of separation on file so that when it is read it comes off the file in the desired format. When the PRINT# command is used with variables, the variables must be separated either with comma, semicolon, or carriage return. The format is:

```
10 OPEN <num>[<dev>]
20 A$=",";B=27.3:C%=7:D$="TERRY"
30 PRINT#<num>,BA$C%A$D$
```

<num> is an arbitrary number 1 to 127 used to reference the opened file.

<dev> refers to the device. (Note: In disk files on the 1541, opening files requires special treatment.) See OPEN.

Print Lines Spacing in BASIC. To get one or more spaces between fields printed by the BASIC programs, a literal of spaces like " " is used. To get several spaces between the printed values of A\$ and B\$ use BASIC statement:

```
PRINT A$ " ";B$
```

See also Print Zones, SPC, TAB (BASIC Functions).

Print Zone To leave space on the print line between items, put an extra comma (,) in the print listing. Enter BASIC statement:

```
PRINT A,,B
```

This would print A in print zone 1, nothing in print zone 2, and put B in print zone 3 (col 29).

Print Zones Each group of 10 spaces across the print line is called a print zone. A comma (,) in a PRINT list of items to be printed means, "Start printing the following item at the start of the next print zone." A semi-colon (;) means the next item is to print immediately after this one, without even a single space between. The print zones begin in columns 1, 10, 20, 30, 40, 50, 60, 70. See also Print Lines.

Printer—Commodore 1525* An impact dot matrix printer that connects directly to the VIC or Commodore 64. It has a 6 x 7 dot matrix and upper and lower case characters without true descenders. It prints unidirectionally, up to 80 columns at 30 cps. It prints 10 characters per inch, or in expanded mode, 5 characters per inch with either 6 lines per inch in character mode or 9 lines per inch in graphics mode. The 1525 uses a tractor paper feed system. The chief advantage is its ability to produce the entire PET graphic character set without any special software.

It contains a 90-byte buffer. In the graphics mode, the user can define special characters. The line and character sizes as well as other modes can be changed by sending specific escape sequences in the form:

PRINT#4, CHR\$(<number>)

The following numbers will set the printer to the appropriate mode:

Graphic Mode	8
Line Feed After Printing	10
Return	13
Double Width Character Mode	14
Standard Character Mode	15
Tab Setting	16
Enter Cursor Down Mode	17
Reverse Field On	18

Using the printers requires opening a channel to it in the format:

```
OPEN<num#>,<dev#>[,<st#>]
```

<num#> is an arbitrary number 1 to 127 used to reference PRINT# statements.

<dev#> is the device number, set to 4 for the 1525.

<st#> is 0 (cursor up mode) for upper case and some graphic characters and 7 (cursor down) for upper and lower case letters.

Printer Buffer Stores data from the computer in its memory and, when the memory is full, sends the data to the printer or modem. See also Buffer, Printer Interfaces.

Printer Interfaces See Buffered Parallel Cable and Driven; Universal Parallel Interface.

Printers See Comstar F/T Super-10" Printer; Deluxe Comstar F/T Printer; STX-80 Printer, Gemini 10x Printer.

Priority Assigned to sprites (q.v.) to organize the order of their appearance. When sprites encounter each other on the screen, the one with the highest priority will appear in front of the other. Sprite 0 has the highest priority and sprite 7 has the lowest.

Probe An electrical device which, by touching a circuit point, allows a test meter to test the circuit's connection and power.

Procedure Part of a structured program which enhances its readability or reliability. The procedure is a separate function of the program and could be incorporated into a subroutine.

Profit Sharing Plan* Helps businesses with pension and other group financial plans. A social security option is available. Disk; printer required. Powerbyte.

Program A sequence of instructions which specify a process for manipulating data. Programs are written in many languages which have level ratings according to how much additional work the processor must do before the program are executed. BASIC is a high level language which requires that all programs be run through a compiler

or interpreter. A mid-range language is an Assembler or Assembly language which is closer to the binary code of the computer, but still needs some processing through an Assembler before execution. The lowest level are programs written in binary or hexadecimal code which are directly executable by the microprocessor. Before Assemblers were developed, all programs were written in binary code.

Program—Line In the program mode, the Commodore 64 saves each BASIC line in RAM. Each line is stored with the line number (entered by the user), a link pointer (points to the next line of BASIC), tokenized BASIC commands (each BASIC command is converted to a two character representation), and the data entered with the BASIC commands. In addition to this, a zero is used between each BASIC line and two zeros at the end of the program.

Program—Mode BASIC commands can be executed in one of two ways: either in direct mode or program mode. In program mode, a line number must precede the instruction. When the user enters the carriage return after entering a BASIC line, the line is stored in RAM. In program mode the microprocessor begins executing the program lines sequentially after the user enters the RUN command and a carriage return.

Program—Source, Object, Executable, Command All programs that are directly executable on the Commodore 64 are Machine language programs written in the numeric instruction code of the Commodore 64's 6510 micro computer chip. Most were originally written by a programmer as text files, known as source programs. The source program contains readable statements in a language such as BASIC. These were then translated by a compiler program, producing an object program.

The object program contains the Machine language instructions for the Commodore 64's 6510, which correspond to the instructions of the original source program. BASIC programs work in this way with a BASIC compiler.

Regular BASIC works in a slightly different way. Regular BASIC is a program (in Machine language) which uses your BASIC program as a guide to what it should do. It is therefore an interpreter, processing each line of your source program and interpreting what should be done. Since it must reinterpret your source program each time you run it, interpreted BASIC can be as much as 100 times slower than compiled BASIC.

When you write a BASIC program, you have produced a source program in text form. The BASIC interpreter, itself a Machine language program, uses your source program as data—a source of instructions or commands to control its execution.

To speed up a BASIC source program by compiling it into a faster Machine language program, you will need a BASIC compiler. The Commodore 64 does not come with a compiler, but they are available from Commodore and various other software houses.

Program—Version or Release. Programs and software packages are changed from time to time to correct errors or add new capabilities. To keep them from being in a constant state of flux and to simplify distribution of modified programs to users, a number of changes are made, tested, and packaged as a new version or release of the program.

Versions or Releases are typically numbered: 1.0 for the first version, 1.1 for the first minor revision, 1.2 for the second minor revision, etc. When a major change or large number of minor changes have been made, a new number is assigned, making Version 2.0.

Program, Object The Machine language instructions which result from translation of a source program by a compiler or Assembler.

Program Counter A register which holds in memory the address in memory of the next instruction to be executed. The counter is incremented each time an instruction is executed. The counter can be modified through sub-routines or calls so that the next instruction executed is not the next one in the program.

Program File Any program created in BASIC in the program mode is saved onto disk as a program file. A program file on disk has with it the location in Commodore 64 memory where it came from and can be returned to that specific location using the load instruction with a 1 in the address argument. The program file is saved on disk one block at a time with the first two bytes of each block pointing to the track and sector of the next block used. Program files are labeled as PRG files in the directory.

Program Integrity Ensuring that programs (or data) cannot be altered improperly. For example, in a payroll system, steps must be taken to insure that employees can not tamper with their pay rates or hours worked. Data security consists of guaranteeing both data integrity and data secrecy or privacy.

Programmable Characters Usually the data required to form the image of a character on the screen is brought from the character generator. This is a list of values that define each character. With the Commodore 64 you can define your character in RAM memory and instruct the computer to look to RAM instead of to the generator when a key is pressed. In this manner you can create your own characters.

Programmers Reference Guide* Directed at users who already have a firm understanding of the BASIC commands on the Commodore 64. It comprehensively explains each of the BASIC commands and explains fully how variables are stored. Includes a less comprehensive discussion of Machine Code instructions and how to execute Machine Code routines. There is some discussion of the user's port and setting up the RS-232 channel as well as using KERNAL subroutines. The reference guide expands on how to use sprites and set the system up for high resolution mode graphics. It discusses memory management and explains, in some detail, the locations of important memory maps like screen memory, color memory, sprite, sound and character memory. Commodore Business Machines, Inc. and Howard W. Sams & Co., Inc.

Programming Language A set of rules specifying a language that can be translated into Machine language and cause the computer to carry out functions.

Programming Languages* See Assembly, BASIC, C, COBOL, FORTARN, Pascal.

Programming Utilities See Assembler64, Assembly Language Debugger; Commodore Pilot 64, Compak, Introduction to BASIC I, KMMM Pascal, LOGO, Simon's BASIC, Tiny BASIC Compiler, Vanilla PILOT.

PROM Programmable Read-Only Memory. ROM which can be modified by the user.

PROM Programmer An external device or module used to write user modified ROMs. The programmer may input data through a hex keyboard, binary paper tape, or directly through the micro-processing unit.

Prompt In general, a prompt is a visual signal from a program to "prompt" the operator to do something. Hopefully, the prompt gives some clue as to what the program requires (or allows) the operator to do in response.

Propagate To go from one component in the computer system to another.

Promqueen/64 A ROM software development system which inserts into the expansion port and includes the software necessary for entering and editing Machine Code instructions from the keyboard. You can copy a program from memory onto EPROMs that insert into the Promqueen. Once copied to an EPROM the program no longer must be loaded from cassette or disk. You can insert your "home made" cartridge and run the program without the delay of loading the program from external

memory, because of an autoloader feature. EPROMs can be purchased separately. The documentation presumes an understanding of memory management of the Commodore 64, but is thorough in its explanations and descriptions. Gloucester Computer Co., Inc.

Propagation Delay The time the processor takes to pass a signal through one device on the system to another.

Proportional Spacing Where the printer allocates horizontal space according to each character's width rather than having a standard width space for all characters. Proportional spacing is more readable than fixed-width type, and appears to be typeset. This is not to be confused with justified type, where spacing is manipulated to produce a flush (even) right margin.

Protected field Some data entry screens have reserved areas that cannot be modified by the user with keyboard entry.

Protector II* Your planet is in danger and a long and difficult conflict is all that can save your people. Synapse.

Pseudo-Instruction A user-defined directive which is interpreted by the assembler as one or more instructions.

Pseudo-Operation (Pseudo-Op) An operation code recognized by an Assembler, but not corresponding to any Machine language instruction. Examples are ORG, which specifies where a program will reside in memory, and SKIP, which specifies a new page in the listing of the program.

PSW Program Status Word. Contains the zero flag, carry flag, and other information relevant to the processor.

Public Domain Programs There are hundreds of programs available in the public domain. The programs are not copyrighted—you can freely copy them and share them with your friends. In most cases these programs have been placed into the public domain, sometimes anonymously, sometimes with the author's name attached. In some cases, the author requests that anyone who finds the program useful send him a "donation" to help pay the costs of development and to finance development of new or improved software. With public domain software, you get a chance to try out the programs extensively without making a commitment to buy. The prices tend to be much lower than commercial software. We urge you to help keep the idea of donation-supported software alive. If you find such a program useful, please send the suggested contribution to the authors, and urge your friends to do the same!

Some of the public domain programs have extensive and excellent documentation. The source code is provided for many of the programs, so you can customize them to suit your needs or preferences. You may encounter a bug in one of the public domain programs. If it is donation-supported, contact the author. Otherwise, you're on your own. Most public domain programs are offered "as is"—if you encounter bugs, it's up to you to fix them.

Pulse A square or gaussian-shaped voltage or current which lasts a short period of time.

Q Register used as an accumulator extension for efficient multiply-divide operations. Usually not found in earlier 8-bit CPUs, which had a combined A register/Q register. Newer 8-bit and 16-bit CPUs usually have a larger set of general purpose registers.

Quad Involving four entities, or a multiple of four.

Quest* You must build an army to search for adventure in this long game. Cassette. Aardvark.

Queue A data structure which contains data or tasks waiting to be processed.

Quick Brown Fox* The Quick Brown Fox is an easy-to-use word processor for the Commodore 64. The manual has an uncomplicated format and step by step training exercises to familiarize the user with word processing. It also points out a few idiosyncracies associated with the hardware. This is aimed at the inexperienced user who might find such problems baffling. The package comes with documentation and plug-in cartridges for both the Vic-20 and the Commodore 64 computers. A demonstration tape is enclosed which contains sample text files. These provide examples of the forms of text that can be created by the Quick Brown Fox. The text entering/editing mode is greatly simplified: a welcome feature for many beginners but tedious for those interested in advanced word processing. For example, the text entering mode is separate from the text edit mode. While entering text, only the previous characters on the same line can be edited. Only in Edit mode can you go to another line and insert or delete characters. Various print and Disk functions are also under strict program control. Quick Brown Fox supports a variety of printers and print formats, and is good for someone unfamiliar with computers and/or word processing. Quick Brown Fox.

Quick Chart* Creates and edits quality data bar-charts. Allows other features such as automatic scaling and specific naming, editing, and reediting values. Disk or cassette. Abacus Software.

Radar Rat Race* You play the rat and must collect all the cheese while avoiding cats and other rats pursuing you down the corridors. Commodore.

Radiation Hardening A quality assurance process used in the production of integrated circuits to select circuits which are better able to withstand radiation.

Ragged Margin Not justified. See Justify.

RALU Register equipped Arithmetic Logic Units. A bit-slice ancestor produced by National Semiconductor.

RAM Random Access Memory. Memory is any device which can store information and allow it to be retrieved when needed. The Commodore 64 relies primarily on random access memory, Read Only Memory (ROM), disks, and cassettes. The term memory by itself is usually a reference to RAM.

RAM is generally made up of a silicon chip consisting of miniaturized circuits. These circuits are composed of electronic gating structures that behave like transistors and are capable of holding a charge. When the voltage is set at the structure and then looked at later it will still have the charge. In this fashion a RAM chip can serve as a memory device. RAM chips are often referred to by the number of bytes (separate charges) that they can hold—such as a 16K RAM chip that would hold over 16,000. Since RAM relies on voltage to maintain the charges, turning the Commodore 64 off will result in a loss of all memory in RAM.

RAM has the advantage of being programmable (the user can enter and change values in RAM).

RAM Disk A block of RAM memory used by a program to simulate a disk drive. The program must modify or intercept all I/O to the “fictitious” drive and redirect it to the RAM memory. The RAM disk will have its own drive letter and appear in every way like a real disk except that it is much faster.

RAM Memory Card A card containing RAM memory to expand the computer’s main memory.

RAM Pack A package containing expansion RAM to mount external to the computer. If mounted inside the computer housing, it would be called a RAM card.

RAMTAS The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL and is used to handle input/output operations. By jumping to address \$FF87, RAMTAS tests RAM, sets the top and bottom of memory, clears address \$0000 to \$0101, clears \$0200 to \$03FF, allocates memory for the cassette buffer, and sets the screen base to \$0400.

Random Access An access method where each data item can be retrieved directly by an address computed from the data.

Random File Disk Drive. A type of disk file in which blocks of data are stored and recalled by drive, track, and sector number. Random files are not given names and essentially are hidden on the disk. The user must keep a record of the track and sector number of data being stored on the disk (often by using a sequential file). Only the Block Availability Map (BAM) has a record of blocks used, and there is no way to know which block is being used by which file.

One can access a block of data within a Random file directly without having to first access the blocks that were written before it. This is much faster and more efficient than accessing information sequentially.

To use a random file safely you must determine which blocks are free to use, or an error message #65 (no blocks) will be displayed. The command channel will also give the next available block.

Once a free block is found, the Block Write command can be used to transfer a block of data from the data channel to the disk.

The format for opening a Random File is:

OPEN <lfn>,<dev#>,<ch#>,"<bu#>"

<lfn> is a logical file number arbitrarily assigned by the user. Its value must lie between 1-255.

<dev#> is the device number of disk drive, usually 8.

<ch#> is the channel number (2-14) assigned by user which serves as a buffer. Data is actually written and read from this buffer and moved one block at a time to and from the disk with disk commands. The symbol lets the disk assign a buffer number.

<bu#> is the buffer number.

See Block Read, Block Write, Block Allocate, Block Free, Buffer Pointer.

Random Number • Read Error

Random Number BASIC. See RND.

Randomize Basic Function. Creates a random floating point number between 0.0 and 1.0 The random number is created by performing a series of operations on a starting number that was created when the system is first powered up. The starting number generated is called a seed and is not directly related to the argument assigned by the user. If the argument is positive the same pseudorandom sequence of numbers is generated each time. If the argument is 0 the random number is generated from the system's internal clock and if the argument is negative a new seed is used to generate a random number each time. The format is:

RND (<num>)

<num> is a dummy number. If this number is negative, a new seed is used to generate a new random number each time the function is called.

Rapidwriter* A word processing program with all the standard features. Disk; printer required. H.D. Manufacturer.

RAS Row Address Strobe. A signal used in dynamic RAMs to reduce the pin count by multiplexing the address.

Raster Register The electron beam of a CRT moves across each row, down a row, and scans again across the next row. It continues this process until the entire screen is displayed. The position of the beam is reflected in a number called the raster count. The raster register can be PEEKed to find the last 8 bits of the raster count. The raster register can be written to with a POKE in order to generate an interrupt when the raster count equals the value on the register.

Raster Scan A standard TV display technique where an image is built from aggregates of dots of varying brightness.

Ratios* Conversion of numeric data to percentages is simplified through this utility program. Disk; printer required. Powerbyte.

R-C Resistor-Capacitor. A circuit connected to an oscillator to define its oscillating frequency. For stable frequencies, a crystal is required.

RD Received Data (RS-232C standard).

RDE Received Data Enable. A status flag in a UART.

RDTIM The name of a machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFDE, RDTIM reads the system clock. Three bytes from the system clock are moved into the accumulator, the X register, and the Y register, sequentially. See KERNAL.

RDY A control signal used with slow memory or devices to indicate valid data is available.

READ BASIC Statement. Reads values from a DATA statement and assigns them to variables. The format is:

READ <variable>[,<variable>...]

<variable> is a numeric or string variable or an array element which is to receive the value read from the DATA table.

A READ statement must always be used in conjunction with a DATA statement. The READ statement will take values read from the data statement and assign them to READ variables on a one-to-one basis. The variable types must agree with the data being stored in them or a "Syntax error" will occur.

One READ statement may access several data statements or several read statements may access the same data statement. If the amount of data available is less than the number of variables allocated for the data, an "Out of data" error occurs. If the number of variables in the READ statements is less than the amount of data items, subsequent READ statements may be used and reading will begin at the first unread element. If there are no subsequent READ statements, the extra data is ignored. Data can be reread using the RESTORE statement. See RESTORE.

READ—Input Data into Memory Data in internal RAM is immediately available to programs for processing. Data in external memory must be copied into internal memory (GET or INPUT), processed, then copied back out to external memory (PRINT).

If data has been created, it can be written out to external memory without a READ first. If data read in from external memory has not been modified, there is no need to write it back out since the original copy is still there.

Read Character from Keyboard BASIC. See INPUT, GET.

Read Data from File BASIC. See GET#.

Read Error An error message from the 1541 drive incurred when the drive is unable to read data on the disk correctly. The 1541 drive is capable of being more specific by reading the error channel (#15) and decoding the error number. The following numbers correspond to the particular error.

20 The disk drive is unable to find the header of a block due to an illegal sector number or corrupted data.

21 The disk drive finds the beginning of a sector by reading a synchronization mark at the beginning. This message appears if the drive can't find that sync mark. It can result from not having formatted the disk (using NEW command) or if the disk is absent or not seated properly. Hardware failures can also give this message.

22 If the disk drive has been given a BLOCK command using random files and the block cannot be found, this number appears on the error channel. The user may have tried to read or verify a track or sector number that does not exist.

23 The disk drive has a method of verifying data as it is read from the disk using a checksum. This message indicates corrupted data or a hardware problem.

24 If a byte read from disk reveals an invalid bit pattern, this error will develop. It can be from a hardware problem.

27 The disk drive has a method of verifying the header information as it is read from disk using a checksum. If there is an error in the header, this message may appear. It can also result from hardware failures.

READST The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFB7, READST moves the contents of the status register into the accumulator. This routine is usually used after an I/O routine to check for any errors. See KERNAL.

Read/Write Describes the nature of an operation, i.e., the direction of data flow.

Real-Time An action or system capable of working at a speed that keeps pace with the occurrence of an actual process.

Real-Time Operating System An operating system capable of real-time task management, including event scheduling, interrupt management, and real-time event counters.

Reasonableness Test A test to determine whether the value of a variable falls within a bracket defined as reasonable. It is used to detect and filter noisy inputs or erroneous outputs.

Record A unit of information, either read, written, or stored, such as a punched card, a disk sector, or a line of characters.

Record Not Present An error message from the 1541 disk drive incurred when the user attempts to INPUT# or GET# data beyond the last record in a file. It can also occur if the user attempts to use the position commands beyond the last record of a relative file.

Rectangular Waveform A rectangular waveform consists primarily of odd harmonics (like the Triangular waveform), but the proportion of the harmonics is reciprocal of the harmonic number. For example, the third harmonic is only 1/3 as loud. See also Harmonic.

Recursive A function, routine, or procedure which calls itself.

REDIM'D Array An error message indicating that an attempt has been made to use the same variable to dimensionalize two arrays. If a variable is used in a program before it is dimensionalized, the computer automatically gives it a dimension of 10. If the program then attempts to dimensionalize the array, the error message will appear. It is best to use the DIM statements in the beginning of a program.

REDO FROM START An error message from the Commodore 64 encountered when user enters string data into an INPUT when the computer was expecting numeric data. If in a program the statement reads INPUT A, the program will prompt for input. If the user enters a word at this point the error message will appear (A is a floating point variable). The user can re-enter the correct input, and the program execution will continue normally.

Reducing Fractions* You battle the computer in an attempt to shrink fractions to their lowest level. Cassette. Comm*Data Computer House.

Redundancy Using more than one of the same item to increase reliability or performance.

Reentrant Programs or routines written in reentrant code. This code can be used by several tasks concurrently.

Reentrant Code A single segment of code and data which is not modified during execution, so that it may be called by multiple programs.

Refresh The logic necessary to rewrite the contents of the dynamic RAM periodically—typically every 1 millisecond (ms).

Refresh Circuitry Electronic circuitry which periodically reads and rewrites the contents of dynamic memory to prevent loss of data. See Dynamic Memory.

Register One word of memory, usually implemented in fast flip-flops, directly accessible to a processor. Most central processing units include a set of internal registers which can be accessed much faster than the main memory.

Register Select One or more lines used to select one register out of a given number within a device. Register select pins are normally connected to the address bus.

Relative Addressing Desired information is located in memory by adding a displacement to a pointer. Addresses are expressed relative to some base address or pointer.

Relative Files Disk file. A type of disk file that allows you to access blocks of information directly. They are similar to random files, but you can alter the record length and name the file. In opening the relative file you assign the record length (up to 255 characters). There can be up to 720 records per file and each record has a position relative to the beginning. This position is assigned using the POSITION command and is in a two-byte format. The format for opening a relative file is:

OPEN <lfn>,<dev#>,<ch#>,<name>,L,">+<CHR\$(<n>

<lfn> is a logical file number assigned by user and referenced when writing or reading from file.

<dev#> is the device number of disk drive, usually 8.

<ch#> is the channel number from 2-14, assigned by user, serves as buffer for data being moved between disk and program.

<name> is assigned by user for file.

<n> is the number from 1-255 assigned by user to determine length of record.

See POSITION.

Release An edition of a software package. Programs and software packages are changed from time to time to correct errors or add new capabilities. To keep programs from being in a constant state of flux, and to simplify distributing

Release—Sound • Reserved Words

modified programs to users, a number of changes are made, tested, and packaged as a new version or release of the program.

Release—Sound The time a note takes to go from sustain level to zero level (silence). See Sustain Sound.

Relocatable The load module or object form of a program or routine which does not contain fixed addresses or which is structured so that it can be "relocated" and executed anywhere in the memory.

Relocating Loader Machine Coded programs which can work in any part of memory are relocatable. Most Machine Codes can't do this because the program references specific addresses. A locatable loader goes through the program and changes the relevant addresses so the program can be placed anywhere in RAM.

Rem A unit of radiation.

REM BASIC Statement. REM is used to insert remarks in programs. The format is:

REM <remark>

<remark> can be any string of characters.

REM statements are nonexecutable statements, but are output exactly as entered when the program is listed. However, they do take up extra memory space and slow execution time. REM statements may be branched into by using GOTO or GOSUB statements. Execution continues with the first executable statement after the REM statement.

The remark, if placed at the end of a statement, must be the last entry on that line.

REM functions differently in Compiler BASIC—For more information see your Compiler Manual.

Remember* A game of memory and concentration for four children. Four levels of difficulty. Recommended for second to sixth graders. Cassette. Comm*Data Computer House.

Removable Media for Recording Information Physical devices for recording information which can be removed from the system, such as cassette and disk. The main medium for Commodore 64 is disk, but cassette, and nonremovable media such as RAM and ROM are also used.

Media classifications are:

a) removable media—disks, cassettes and some hard disks, or

b) fixed media—most hard disks. Fixed media are not removable from the device that drives them, so there is no ability to store additional data or backup copies off-line (outside the computing system) for insertion when needed. See also Memory.

REN CP/M. Command used to REName disk files. The format is:

REN<new filename><old filename>

See also CP/M Commands.

RENAME Disk Command. The RENAME command, when sent through the command channel, changes the name of a file in the disk directory. The format is:

OPEN15,8,15

PRINT#15,"RENAME0:<newname><oldname>"

<newname> is the new name of file arbitrarily assigned by the user.

<oldname> is the name of the file being changed.

RES RESet signal. An input line into the 6510 microprocessor that STARTS the microprocessor from a power down condition. Memory is retained on BASIC RAM.

Research Assistant 2.0* This filing system is for students writing reports and theses. The program disk comes with a "build" program that creates, updates and prints files and a "cross reference build" program that is used to build a cross reference file using keywords and dates. The programs are written in BASIC and use sequential files to store and retrieve records—features that considerably slow the entering/editing and printing function (in other words the overall performance of the system as an effective, time-efficient record-keeping system). The program is menu-driven and has options to support a variety of printers. The report format for the printer is built into the program and therefore limits its application as a good general purpose database. TOTL Software, Inc.

Reserved Device Numbers The Commodore 64 has assigned certain numbers to specific devices. The numbers must be used when opening a channel to the device. The printer is device 4, the cassette device 1, the screen device 0. A single 1541 disk drive is device 8. If more than one 1541 is used, it is necessary to change the device number of the second drive.

Reserved Words BASIC. Reserved words have particular meanings in BASIC and are used for commands, statements, functions, and operator names. These words cannot be used as variable names, and variable names cannot be reserved words followed by a type declaration character (\$, %).

The reserved words are separated with space or spaces around them so that they are easily recognized by BASIC. If you accidentally use one of the reserved words, you may see an error message or have strange results when you execute the program.

The following are reserved words in BASIC for the Commodore 64:

ABS	AND	ASC
ATN	CHR	CLOSE
CLR	CMD	CONT
COS	DATA	DEF
DIM	END	EXP
FN	FOR	FRE
GET	GET#	GOSUB
GOTO	IF	INPUT
INPUT#	INT	LEFT
LET	LEN	LIST
LOAD	LOG	MID

NEW	NEXT	NOT
ON	OPEN	OR
PEEK	POKE	POS
PRINT	PRINT#	READ
REM	RESTORE	RETURN
RIGHT\$	RND	RUN
SAVE	SIN	SGN
SPC	SQR	STATUS
STEP	STOP	STR
SYS	TAB	TAN
THEN	TIME	TIME
TO	USR	VAL
VERIFY	WAIT	

Reset To return to zero, or to some arbitrarily selected beginning point. Powering on the Commodore 64 performs a reset.

Reside Be recorded in. A program may reside on a disk or in memory (RAM or ROM).

Resident Software A program which resides in the main memory of the system.

Restart To restart a program after it has been stopped with the run/stop key, hit Shift run/stop or enter CONT and hit carriage return.

RESTOR The name of a Machine language subroutine within the operating system of the Commodore 64. It is part of a group of subroutines referred to as the KERNAL to handle input/output operations. By jumping to address \$FFBA, RESTOR restores the default values of system vectors used in BASIC and KERNAL routines. See KERNAL, ST.

RESTORE BASIC Statement. RESTORE lets you reread DATA statements. Following the execution of the RESTORE statement, the next READ statement reads the first item in the first DATA statement in the program.

Restore Key The Restore key, pressed in conjunction with the RUN/STOP key, will halt execution of the program, clear the screen, and return the system to its original state (warm start). It does not alter a program already in memory.

Retrofit To improve or change software or hardware by making additions.

RETURN BASIC Statement. Brings you back from a subroutine. Used in conjunction with the GOSUB statement. See also GOSUB and RETURN.

Return Key Pressing the return key returns the cursor to the left edge of the screen and moves it down one line. In the direct mode (without program line number) a return sends the entire line to the interpreter where it is translated into Machine Code and executed immediately. In the program mode the return tokenizes each of the BASIC commands, sets up link pointers, and moves the line into BASIC RAM. Pressing RETURN while the cursor is on a line that contains a BASIC command, regardless of where the cursor is, enters that line. If there is a program line number with no commands following it, a RETURN on that line will

erase any line in the program that has that number. In this way program lines can be deleted from a program. The RETURN can be executed in a program using:
PRINT CHR\$(13).

Return Without GOSUB An error message from the Commodore 64 encountered when a program reads a RETURN statement and has no GOSUB to return to.

Reverse Video The ability of some CRT terminals to display dark characters on a light background as opposed to the standard light on dark. Also called Inverse Video. Obtained by pressing CTRL and RVS On Keys simultaneously.

RF Modulator Encodes a composite video signal, as required for most monitors, into a radio frequency signal for display on a standard television set.

RFI Radio-Frequency Interference. Most electronic devices emit radio frequency waves. These frequencies may interfere with the workings of other devices. The Commodore 64 and its peripherals may generate enough RFI to interfere with a nearby TV or radio.

RI Right In. The right incoming bit to fill the vacancy left by shifting all other bits in the word to the right.

RIGHT\$ BASIC Function. RIGHT\$ returns the rightmost <n> characters of string x\$. The format is:

<V\$> = RIGHT\$(<x\$>, <n>)

<X\$> may be any string expression.

<n> is an integer expression specifying the number of characters to appear in the result.

If <n> is greater than or equal to LEN(X\$), then X\$ is returned. If <n> is zero, the null string (length zero) is returned.

See also MID\$ and LEFT\$

Right Arrow (→) When the right arrow key is pressed the cursor moves one character to the right. This function is common in text entry and in entering commands. This key may be defined differently by various application programs.

Ring Indicator In telephone based applications, such as telecommunications via modem, Ring Indicator is the signal or line which causes the bell to ring.

Ripple-Carry An addition technique where the carry coming out of an adder is propagated to the next adder. A faster method is to use carry look-ahead.

Rise Time The time required to complete the low-to-high transition of a pulse.

RND BASIC Function. RND function returns a random number between 0.0 and 1.0. The format is:

V = RND(<x>)

<x> is a numeric expression which affects the returned value as follows:

The same sequence of random numbers is generated each time the program is run unless the random number

generator is reseeded. If $\langle x \rangle$ is positive or not included, $RND(\langle x \rangle)$ generates the next random number in the sequence. $RND(0)$ repeats the last number generated.

To generate random numbers in the range zero through $\langle n \rangle$, use the formula:

$INT(RND(0) * \langle n+1 \rangle)$

RO Right Out. The right output from a shifter.

ROL ROTate Left one bit. An Assembly language instruction for the 6510 microprocessor that shifts the bit pattern of the word specified by the argument one bit to the left. The carry flag bit is moved into the rightmost bit of the word, and bit seven moves into the carry flag bit. The addressing mode for the argument may be zero page, zero page X, absolute, absolute X, or the argument could be the letter A for accumulator. The sign flag bit, the zero flag bit, and the carry flag bit can be altered by the instruction.

Rollover Depressing two or more keys on a keyboard simultaneously. A good keyboard controller will include debouncing and multiple-key rollover protection. See Bounce, Keyboard.

ROM Read-Only Memory. Memory that can be written only once. ROM is generally comprised of Silicon chips composed of electronic gating structures. When powered on, these gating structures are capable of holding a charge. Applying a strong enough charge can irreversibly alter these gating structures, so that when the chip is powered up again each structure appears to have the same charge as before it was powered down. In this way the device can serve as a memory device. ROM cannot be altered once the memory has been burned into it. The Commodore 64 comes with over 20K of ROM which contains the operating system, the BASIC interpreter, and the kernel for the system.

ROM Image The ROM responsible for determining the structure of characters is located in the character generator. The actual location of this part of ROM is addresses 53248 to 57343. The VIC-II chip can access 16K of memory at a time. To have access to the character generator the Commodore 64 makes use of ROM image. The Computer assigns a ROM address identical to a RAM address. The user may enter data into the RAM without, of course, changing the ROM. When the computer needs access to the ROM, it disconnects the RAM for a moment and takes the data it needs from ROM. When the user needs data from the RAM, the computer disconnects the ROM.

ROMable Code which will execute properly when placed in ROM is ROMable; segments of ROMable code have no temporary data storage areas and do not use instruction modification techniques.

Roman Numerals* Teaches Roman numerals and how to change them to Arabic. For fourth to eighth graders. Cassette. Comm*Data Computer House.

ROR ROTate Right one bit. An Assembly language instruction for the 6510 microprocessor that shifts the bit pattern of the word specified by the argument one bit to the

right. The carry bit moves onto bit 7 of the word and bit 0 moves into the carry flag bit. The addressing mode for the argument may be zero page, zero page X, absolute, absolute X, or the letter A for accumulator. The sign flag bit and the zero flag bit can be altered by the instruction.

ROTATE Shifts the contents of a register or word to the left or right. The bit coming in one end of the rotating word is generally the one falling off the other end. Sometimes, it is the old value of the carry bit (9-bit rotation).

Round-Robin A scheduling technique in which a task list is cycled through from top to bottom and back again. In round-robin scheduling, each process or device corresponding to a task is guaranteed periodic service whatever the actual task traffic may be.

Routine A section of code written to perform an action, such as an input character routine, or a disk write routine.

Row Scanning A technique used in decoding which key of a keyboard has been pressed. Each row is scanned in turn. The output on the columns is examined, resulting in identification of the key. See also Line Reversal.

RS Register Select. A control signal determining which of several eligible registers will be used in an MPU operation.

R-S Flip-Flop A flip-flop using two cross-coupled NAND gates.

RS-232 for the Commodore 64 The Commodore 64 has a built-in RS-232 interface accessed through the user's port. The voltages of the port are not standard RS-232 voltages and an interface is required before connecting to any RS-232 device. Because of hardware constraints, information cannot be received across the RS-232 port while cassette or serial bus activity is occurring.

Information from the RS-232 port can be received into a buffer with the appropriate downloading program and then sent to the cassette or disk with the appropriate software. See Download.

Before an RS-232 port is used, the channel must be opened appropriately. The Baud rate of data that will be transmitted, the parity, the word length of data, the state of duplex, and the stop bits can be sent when opening the channel or by POKEing the appropriate numbers into the appropriate memory locations (referred to as command and control registers).

When an RS-232 channel is opened, two 256-byte buffers are created in memory that are used for data being sent in or out of the channel. An automatic clear is executed when opening the channel, so arrays or variables can only be

created after the channel is opened. If there is an error in the initial transmission to the command or control registers, the system may default to 50 baud. Information sent to the RS-232 channel enters the buffer and is sent out through the port using standard EIA RS-232-C handshaking configuration. Closing the channel eliminates all information in the buffers whether it has been transmitted or not. The format for opening an RS-232 channel is:

```
OPEN <lfm>,2,0,<chr$(n)><chr$(a)>
```

<lfm> is an arbitrary logical file number (1-127) assigned by user to reference this channel during PRINT# or GET# statements.

<n> will determine the baud rate, word length, and number of stop bits that will be used by the channel. The number is sent to the Control Register 665.

<a> will set the parity and duplex used by the channel. The number is sent to the Command Register 666.

RS-232C Widely used standard for connecting computer system components, especially for serial communication of control and data between computers and serial input/output peripheral devices. RS-232C is an electrical standard for connecting data terminal equipment such as modems or network data concentrators. It allows substantial variation as to what signals are passed.

RTI ReTurn from Interrupt. An Assembly language instruction for the 6510 microprocessor that pops the top word of the stack and moves it into the status register and then pops the next two words and moves them into the program counter. The stack pointer is adjusted and none of the flag bits are affected.

RTOS See Real Time Operating System. An operating system in which data and computer response proceed at the same rate.

RTS Ready To Send (RS-232C standard signal).

RTS ReTurn from Subroutine. An Assembly language instruction for the 6510 microprocessor that pops the top two words from the stack and moves them into the program counter. The program counter is then incremented by one. This instruction can be used to return from a subroutine following a JSR instruction. None of the flag bits are altered.

Satellite Processor A computer subordinate to another computer, possibly communicating over large distances, which performs specialized processing related to the master computer. The satellite may also be contained in the same device as the main processor, creating a multi-processor machine.

SAVE The name of a Machine language subroutine within the operating system of the Commodore 64. It is part of a group of subroutines referred to as the KERNAL and used to handle input/output operations. By jumping to address \$FFD8, SAVE copies consecutive bytes of data from memory to a device specified. The accumulator and X and Y registers are loaded with the low and high byte of the end of memory being copied. The SETLFS and SETNAM

routines must be used prior to using the SAVE routine. See KERNAL.

SAVE BASIC Command. Copies the program currently in main memory onto a mass storage device such as a disk or cassette. The program, after being saved onto tape or disk, still remains in the main memory. The format for the command is:

SAVE"<name>",<dev>,addr

<name> is the name the user assigns to the program file and the one that will be used to load the program at a later time. On the 1541 disk drive, the name is compared with those in the directory to be sure that name isn't already in use. The drive also determines from the Block Availability Map (BAM) whether there is enough space remaining on the disk to save the entire program. On the cassette, the file name is optional.

<dev> is the device number. On a single disk drive this will be the number 8. When saving from cassette the device number is 1. If this number is left out the default value is 1.

<addr> is used for cassette operation. A "1" lets the cassette know the address from which it is being saved so that it can be loaded there at a later time, a 2 will create an end of tape marker at the end of the program being stored, and a 3 combines both functions.

SAVE CP/M. This command saves a program or file on disk in the Transient Program Area (TPA). The pages (p) to be saved are specified in the argument. The format is:

SAVE p <filename>

p = 256 byte segments (pages).

See also CP/M Commands.

Savings Account Miser, The* Helps you analyze various types of savings accounts with compound interest. Can be very useful for computing retirements and IRA yields. Powerbyte.

Sawtooth Waveform A sawtooth waveform consists of all harmonics, each in proportion to the reciprocal of the harmonic number. For example, the third harmonic will be only 1/3 as loud as the fundamental frequency. See also Harmonics.

SBC Single Board Computer. A name applied to a line of board-level products built to Intel specifications and using a common system bus known as the multibus. This bus is standardized as the IEEE 796. National Semiconductor has a compatible board line designated by the letters BLC (Board-Level-Computer).

SBC SuBtract with Carry. An assembly code instruction for the 6510 microprocessor that subtracts from the accumulator the data specified by the argument with borrow. The result of the operation is placed into the zero page X, absolute, absolute X, absolute Y, (indirect S), or (indirect) Y. The sign flag bit, the zero flag bit, and the carry flag bit are affected by the result. SBC may be in decimal or

binary mode depending on the appropriate bit setting in the status register.

Scheduling Allocating a non-shareable resource, such as CPU time, or an I/O device to a particular task for a period of time.

Schotky A technology of high-speed circuits.

Scientific Applications Software See Engineering-Mechanical-Scientific Applications Software.

SC/MP Simple Cost-effective MicroProcessor. National Semiconductor's small 8-bit microprocessor.

SCNKEY The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FF9F, SCNKEY checks the keyboard and moves the ASCII value of any key pressed into keyboard queue. Normally the Commodore 64 automatically executes this routine when the keyboard generates a IRQ. The user can utilize this routine if the IRQ is disabled. See KERNAL.

Scope The scope of a variable is comprised of the sections of a program where that variable is available to the user. Also, an abbreviation for oscilloscope.

Scotch A brand of magnetic recording media.

SCR Silicon Controlled Rectifier. A silicon cell which permits current flow in one direction only, thus effectively converting AC current to DC.

SCRATCH Disk Command. When sent through the command channel, the SCRATCH command channel, erases specified files and programs on the disk. Programs can be erased one at a time or in groups using pattern matching. The format is:

OPEN15,8,15 PRINT#15,"SCRATCH0:<name>"

<name> is the name of file to be erased from disk.

Scratchpad A group of general purpose registers without specific function that serve as a high speed workspace for some operations. Usually, it is an internal RAM, faster than the main system RAM.

Screen ECHO Function. This sends keyed characters to the screen for a visual confirmation of what has been typed. There is no hard-wired connection between the keyboard and the screen. The keyboard simply enters characters into memory. The Screen Editor of Commodore 64 copies the characters from memory to the screen, creating a duplication or "echo" of what was keyed.

SCREEN The name of a Machine language subroutine within the operating system of the Commodore 64. It is part of a group of subroutines referred to as the KERNAL and used to handle input/output operations. By jumping to address \$FFED, SCREEN returns the format of the screen (number of columns and rows) into the X and Y registers. See KERNAL.

Screen The surface of a monitor or TV set on which characters are displayed.

Screen Display To freeze or hold the screen display while the operator reads a message, write a delay loop after printing the message.

Example:

```
1000 FOR Y = 1 TO 2000 1010 NEXT Y
```

To freeze the screen until the operator is done with it, put in a dummy input statement and instruct the operator to press ENTER to proceed. The input variable need not be used in your program:

Example:

```
1000 INPUT "Press ENTER to continue";A$
```

Screen Display Codes The Screen Codes for the Commodore 64 are listed in the following table. It shows the number to be POKEed into the screen memory (1024-2023) to get the desired characters on the screen at the corresponding locations:

Screen Editor The screen editor is a program that arranges the display of characters entered from the keyboard to the screen. It allows for inserting and deleting characters and is built into the ROM of the Commodore 64.

Screen Generator Helps define CRT screen forms, which are a particular pattern of symbols on a CRT screen, for data entry and display. Screen forms are often displayed in protected fields and consist of prompts to help the user enter data.

Screen Memory A 1,024-byte area starting at address 1024 to 2047 (HEX \$0400 to 07FF). Each of these locations is 8 bits wide. Each location can hold any integer up to 255. The location of screen memory can be changed by a POKE to the control register at 53272 (\$D018 HEX) addressing the upper 4 bits. For example:

POKE 53272, (PEEK(53272) and 15) or A.

Screen Size A measure of the amount of information that a CRT screen can display. Screens may be measured diagonally, like TV sets, or by the number of vertical and horizontal dot or character positions.

Screen-Graphics-64* SG-64. Graphics Utility program. A Machine language program that wedges itself into Commodore's BASIC. These commands may be used in standard BASIC programs and are executable if the SG-64 has been loaded into computer memory. The SG-64 Interpreter allows the user to access the high resolution graphics features of the Commodore-64 from BASIC programs using simple commands. The package comes with an easy to follow manual, a demo program that contains samples of graphics images, and a tutorial program that has step-by-step instructions on how to create different types of graphics images on the screen. The program also has facilities to build and animate sprites. Abacus Software.

Screenmaker* An 80-column video board that gives your system a full screen of characters. Includes software to connect the system. 2K video RAM. Microtech.

Script Ease* Script Ease provides the user with elementary training in word processing. It is available in compiled BASIC, offering considerable speed and performance as compared to other programs available in BASIC. The package includes documentation and a disk containing the word processing program and sample text letters. The sample letters illustrate the features of the word processor (including Mail Merge). The simplified documentation and the menu-driven program are easy to learn. The program supports many editing/formatting features and can be used for output of routine correspondence. The program has built-in default values for various print formats so the user can print well formatted hardcopy without defining specific format. It can also access the disk directory without erasing text in current memory. Midwest Software.

Scrolling Moving the entire screen in one direction, one pixel at a time. The VIC-II chip on the Commodore 64 supports scrolling in both the vertical and horizontal

direction. Address 53270 enables scrolling in the X direction and 53265 enables scrolling in the Y direction.

SE Sign Extend. Used during a multiply or divide operation and during some shift operations to insure that negative numbers remain negative when shifted right. The convention is that the bit shifted into the high end of the register will be identical to the bit that was in the high order position when the shift began.

Sea Wolf* You are the captain of a submarine patrolling a dangerous section of enemy coastline. Commodore.

SEC SEt Carry. An assembly code instruction for the 6510 microprocessor that sets the carry flag bit to one. Only the carry bit is affected.

SECOND The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FF93, SECOND sends a secondary address to an I/O device following the LISTEN routine. The secondary address is loaded into the accumulator prior to using this routine. See KERNAL.

Sector A continuous section of a disk track. A block of data on a disk is addressed by its track and sector numbers. Typical disk sector sizes are 128, 256, or 512 bytes of data. Consecutively numbered sectors may or may not be physically adjacent within a track. The 1541 Disk Drive uses 256-byte sectors written 17 to 21 per track.

Sector, Bad A sector on the disk which will not read/write data correctly. Usually due to a minor physical flaw in the disk. One or two bad sectors will not seriously affect the disk's usefulness—DOS will mark them as bad and avoid using them. More than a few bad sectors indicates the disk should be used as a frisbee rather than to hold your valuable data.

Sector Five* You must guess how many attackers there are to send them back to their own planet and save the universe. Cassette. Micro-Ed.

Sectors The 1541 saves data onto a disk in a very specific format. Data is saved in concentric rings called tracks. Each ring or track is divided into sections called sectors. Each sector contains 256 bytes of information. When a new disk is inserted for the first time, the tracks and sectors are labeled using the NEW command. See NEW. Disk Command. This command must be issued before data can be stored on a disk. When data is saved on a disk, the sectors that are used are reported in the Block Availability Map (BAM) located on the disk. Prior to writing to a disk, the disk drive automatically checks the BAM to make sure the sector it is about to write on is available. See Disk.

SED SEt Decimal mode. An assembly code instruction for the 6510 microprocessor that sets the decimal flag bit to one. This allows for decimal operations with the ADC and SBC commands. Only the decimal flag bit is affected.

Seek Time The time needed to position the head of a disk over the specified track.

Segment A continuous block of memory addresses, such as 0 to 64K.

SEI SEt Interrupt disable. An assembly code instruction for the 6510 microprocessor that sets the interrupt flag bit to one. This prevents any further interrupts. Only the interrupt flag bit is affected.

Semicolon (;) DOS Command Delimiter. Parameters on DOS commands can be delimited (separated) by any of these characters: space, comma, or semicolon.

Sensor A device which translates a physical stimulus into an electronic signal which may be input into a computer.

Sequencer In a bit-slice system, the module in charge of providing the next microprogram address to the microprogram memory. It is essentially a complex multiplexer, but may include stack facilities and a loop counter.

Sequential Access An access method in which items may only be accessed in a fixed order. The standard example of a sequentially accessed medium is magnetic tape. Here, in order to access a particular record, all records before it must be scanned first.

Sequential File A file whose elements may only be accessed in ascending order. To read an element of a sequential file, all of the preceding elements must be read.

Sequential Files 1541 Disk Drive. A file where data is moved through a buffer in the same order each time it is accessed. If there are ten characters to be written into a sequential file, each character is stored onto the disk in order from one to ten. To access any character in that file you have to access each character before it in the same order it was written. Opening a sequential file includes naming the file, indicating that it is a sequential file and declaring whether you are going to write to or read from the file. The PRINT# statement is used to write to a sequential file and it is vital that separate items be delimited with commas, semicolons, or carriage returns. Data from a sequential file is read using the GET# or INPUT# statement. The format for opening a sequential file is:

```
OPEN <f#>,<dev#>,<channel#>,"0:<name>,<type>,<direction>"
```

<f#> is an arbitrary number from 1 to 127 assigned by user and referred to any time data is written or read from file.

<dev#> is the number of disk drive. Usually 8.

<channel#> is an arbitrary number 2 through 14 used by DOS for setting up buffer. Only one file per channel at a time.

<name> is assigned by user and recorded in directory.

<type> of file. For sequential enter S.

For the <direction> of a sequential file either W for write or R for read.

Serial For sequential handling of processes, transmissions or storage of data. Serial means moving information one bit at a time, usually where only one data wire is available. The 8 bits of a byte are transmitted one after another in series. The I/O device must collect 8 bits sequentially to make one byte.

Serial Bus The serial bus of the Commodore 64 is accessed through the 6 pin DIN socket on the rear of the computer. It is connected directly to the 1541 disk drive or 1525 printer. Some companies manufacture interfaces which are compatible with the serial bus and convert data transmitted to more common formats, such as the CARDCO interface which converts the serial bus data to a Centronics connection. The serial bus can be used to daisy chain up to 4 disk drives and a printer. Each device must have its own device number from 4 to 31 to avoid confusion when data is transmitted. Common device numbers include 4 for printers and 8 for a single disk drive. When a user opens a file for a device on the serial bus the computer sends the device number to the bus where all devices receive the address simultaneously. The device with the corresponding number responds and begins receiving or transmitting data. The format for opening a device on the serial bus is:

OPEN <f#>,<dev#>,<n>

<f#> is an arbitrary number assigned by user to reference PRINT#, GET#, or INPUT# statements.

<dev#> is the number hardwired or programmed into a peripheral device.

<n> is a secondary address number used by some peripherals.

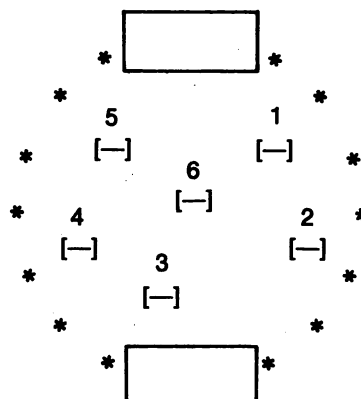

Serial Data Data transmitted sequentially, one bit at a time.

Serial Port An I/O port through which data is transmitted and received serially. The data is sent one bit at a time, as opposed to a parallel port that can send 8 bits at a time. The Commodore 64 utilizes a serial port to connect to the 1541 disk drive or some printers. The port is a 6 pin DIN socket located in the back of the Commodore 64. The port gives access to the serial bus which connects to the CIA (Complex Interface Adapter). Five drives can be connected to each other with the last one connected to the port in a daisy chain configuration. Each drive must have a different programmed device number. Data sent to the serial bus is available to all the drives but only the ones with the device number specified in an open statement will receive or transmit data. Since there is essentially only one line in which data is being transmitted the microprocessor must control whether data is to be sent or received. It does this by sending a command to a device and specifying that the device is to TALK or to LISTEN. All data being transmitted is synchronized from a clock in the system and clock signals are also transmitted through the serial bus. When serial data is received in the CIA, it is converted to parallel data and made available to memory and the microprocessor. Likewise data from internal memory starts as parallel data and is converted to serial data in the CIA. See CIA.

A table of the Serial Port follows:

SERIAL I/O

PIN	TYPE
1	SERIAL SRQUIN
2	GND
3	SERIAL ATN IN/OUT
4	SERIAL CLK IN/OUT
5	SERIAL DATA IN/OUT
6	RESET

Serial Printer Any printer that receives data serially is called a serial printer. Although there may be more than one line to the printer, data is sent one bit at a time. The 1525 printer is a serial printer.

Series Circuit elements connected so that the output of one is the input of the next.

Servo Short form of servo-mechanism (q.v.).

Servo-Mechanism A device which converts electrical signals to mechanical or physical actions. Servo-mechanisms range from simple relays to robots.

SETLFS The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address \$FFBA, SETLFS sets up a logical file number, a device address, and a secondary address. It is used prior to many of the other KERNAL routines in establishing a file table. Prior to using this routine, the accumulator must be loaded with the logical file number, the X register with the device number, and the Y register with a secondary address. The Y register should be loaded with 255 if there is no secondary address.

SETMSG The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle Input/Output operations. By jumping to address \$FF90, SETMSG can enable error and control messages. If bit 7 of the accumulator is 1, error messages from the KERNAL are enabled. If bit 6 is set, control messages are enabled.

SETNAM The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle Input/Output operations. By jumping to address \$FFDB, SETNAM sets up a file name to be used by the OPEN, SAVE, and LOAD routines. Prior to using this routine, the accumulator must be loaded with the length of the file name and the X and Y registers must be loaded with the address of the start of the file name.

SETTIM The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle Input/Output operations. By jumping to address \$FFDB, SETTIM sets the system (jiffy) clock. The clock increments one every 1/60th of a second and uses three bytes to count the increments. The clock is set by loading the accumulator with the most significant byte, the X register with the next most significant byte, and the Y register with the least significant byte. These registers must be loaded prior to using this routine.

SETTMO The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle Input/Output operations. By jumping to address \$FFA2, SETTMO sets a timeout flag for an IEEE device on an IEEE interface card. Bit 7 of the accumulator is loaded with a 0 to enable the timer, a 1 to disable the timeout. With the timeout enabled, a IEEE device must respond within 64 milliseconds with a "Data Address Valid" signal or an error condition will occur.

Setup Time The time required before a signal can be changed from its prior state. Also, the time required to set up the preliminary conditions necessary to run a program.

SGN BASIC Function. Gives the sign (positive or negative) of (x). The format is:

$v = \text{SGN}(\langle x \rangle)$

$\langle x \rangle$ may be any numeric expression.

If $\langle x \rangle$ is zero, $\text{SGN}(x)$ will return 0.

If $\langle x \rangle$ is negative, $\text{SGN}(x)$ will return -1.

Shift Most keys on the Commodore 64 are capable of displaying two characters, upper and lower case, and two graphic symbols. Pressing the shift key while the computer is in upper/lower case mode gives the upper case letter. In the upper case/graphic mode it gives the PET graphic symbol to the right of the key.

Software Computer programs of all kinds are called software. Hardware is the chips, wires, boards, etc., which make up the computer. A special case is Read-Only Memory (ROM), which is hardware that contains a permanent copy of software. Shorthand terminology here could be confusing—"A BASIC ROM" means a ROM (hardware) containing a copy of a BASIC interpreter program (software). Such ROMs are often called firmware to distinguish them from non-program hardware and from software in changeable media (RAM, disk, cassette, etc.) See ROM, RAM.

Software, Applications A Software package is a group of computer programs, possibly including data files and documentation, which perform a function or group of related functions on the computer. These are called applications software when the programs are devoted to an end-user task, such as a word processing package or an accounting package. These programs are called systems software packages when they facilitate the use of the machinery, such as a disk operating system or a program development package.

Software, Operating System The operating system for the Commodore 64 is located in internal ROM. Some systems require loading the operating system from disk. The Commodore 64 allows for loading CP/M, an alternative operating system requiring a CP/M cartridge. See Operating System.

Software Package A pre-written group of commercially available programs which serve a specific need, such as word processing, inventory control, or database management.

Source Drive The disk drive from which information/data is coming. Target drive is the disk drive to which information/data is going.

Source Language The original language used by the programmer, on which a translator program operates to produce a version in the language used by the machine.

Source Programs A file which contains data to be processed by a language processor, interpreter or compiler. All programs that run directly on the Commodore 64 are Machine language programs (in the actual numeric instruction code of the Commodore 64 6510 microcomputer chip). Most were originally written by a programmer as source programs.

A BASIC compiler is a Machine language program which turns a source program into Machine Code. When you run a BASIC program on a system with a BASIC compiler, the compiler translates your source program into an object program. The object program is stored for reuse, and the source program does not need to be compiled again.

You will then use the LINK program to further process the object program (identified by the suffix .OBJ) into an executable file (identified by the suffix .EXE). The resulting program is no longer a BASIC program, but a Machine language program which is based on (is a translation of) your BASIC source program.

The BASIC interpreter is a Machine language program which uses your BASIC program as a guide to what it should do. It processes each line of the source program and interprets an object code instruction. Since it must re-interpret your source program each time you run it, interpreted BASIC can be as much as 100 times slower than compiled BASIC.

Source, The* One of the largest subscription information networks in the country. Personal computer users may access it over the phone lines through the use of a modem. vious consecutive years for any stock of interest: net worth before taxes, gross sales, earnings per share, book value, high stock price, low stock price, and dividends. The program then calculates percentages for revenues, earnings per share, pre-tax profit, amount earned annually on invested capital, average payout, the average and current yield, highest and lowest price earnings ratio, the average high and low price earnings ratio, the annual high and low price earnings ratio, and the annual percentage payout and yield. The user is asked to forecast a future high earnings per share, a future low earnings per share, and a future low stock price. From this, the program calculates buy and sell ranges and up-side/down-side ratios. This program only allows for annual statistics and is therefore better suited to "fundamental analysis" than to "technical analysis." The program can output to a printer and actually display bar graphs. Values entered must be in decimal form. Printer required. Custom Software Design.

Stock Market Software See Stock; Stock Ticker Tape, The; Super Broker, The.

Stock Ticker Tape, The* Turns your computer into a tool for collecting information on the stock market and other investments. Also has the potential to tie into large databases for financial updates. Disk; printer required. Powerbyte.

STOP The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle I/O operations. By jumping to address \$FFA2, STOP checks to see if the stop key was pressed during a UDTIM routine. If the stop key was pressed, the Z flag is set; if not, the accumulator contains a byte representing the last row of a keyboard scan. See KERNAL.

STOP BASIC Statement. The STOP statement terminates program execution and returns to command level. The format is:

STOP

You may use STOP statements anywhere in a program to stop execution. When BASIC sees a STOP statement, it displays the message:

Break in <xxxxx>

<xxxxx> is the line number where the STOP occurred.

STOP statements do not close files, as do END statements. BASIC will always return you to command level following execution of a STOP statement. By using the CONT command, you can resume execution of the program. See CONT.

STOP statement functions differently in Compiler BASIC. See your Compiler Manual for more information.

Stop BASIC Program see STOP and END.

Stop-Bit In some computers, bytes of data sent to or from the system must be prefaced with blank bits. These bits are called stop bits. Usually either one or two are

required. If the Commodore 64 is connected to another system requiring these stop bits for RS-232 transmission, they can be programmed by using the control register address 659.

Storage Synonym for Memory.

Story Problems in Addition and Subtraction* A series of stories in a medieval setting that contain math problems. It takes concentration and understanding to master this program, but the computer can be used for assistance. Cassette. Micro-Ed.

STR\$ BASIC Function. STR\$ function returns a string representation of the numeric value in <x>. The format is:

v\$ = STR\$ <x>

<x> is any numeric expression.

When <x> is positive, the string returned by STR\$ contains a leading blank (the space reserved for the plus sign).

Strain Gauge A sensor which produces a voltage or resistance change when a force is applied.

String An ordered sequence of data items, such as characters. For example, the word "string" is a string of six characters. See Character String.

String, Length of See LEN.

String, Numeric Value of See VAL.

String Data String variables and constants refer to groups of characters, either alphabetic or numeric. Though they may contain numbers, they are viewed by the computer as symbols without value. These characters can be concatenated and compared, but cannot have arithmetic operations performed on them. They are recognized by either being in quotation marks or as variables ending in the % sign. The expression "27"*"2" or A\$*B\$ has no meaning. The expression A\$ + B\$ will concatenate the two strings to yield a third string. The two strings are equal if they match character per character.

String Handling The ability of a programming language to operate on strings of characters.

String Too Long An error message generated by the Commodore 64 when a string greater than 255 characters is read. Be sure that when you input multiple variables, you include delimiters (commas, semicolons, or returns) between variables.

String Variable BASIC. String variable names (for characters) must start with a letter and can have up to 40 characters (but only the first two are considered). Also they must not use any reserved words, such as: IF, ON, THEN, GOTO, etc, or a reserved word followed by a type declaration character (\$, %). String variables can hold 0 to 255 alphabetic, numeric, or special characters. See Reserved Words for a complete list of BASIC reserved words.

STRINGS BASIC Function. Gives a string of length <n> whose characters all have ASCII code <m> or the first character of x\$. The format is:

v\$ = STRING\$(<n,m>) v\$ = STRING\$(<n,x\$>)

<n,m> must be in the range 0 to 255.

<x\$> can be any string expression.

<v\$> is a variable.

Strobe A selection signal that is active when data is correct on a bus.

Structured Language A computer language which aids or enforces structured programming. Control structures such as IF...THEN, ELSE, DO, WHILE, CASE and REPEAT, UNTIL, together with provisions for declaring logically separate program modules such as procedures, and limiting the scope of variables, all lend a modular structure to programs. Unconditional control transfer statements are often left unexecuted. Some popular structured languages are Pascal, ALGOL, and BASIC.

Structured Programming A set of techniques that improve the reliability and comprehensibility of programs by increasing programmer discipline. Structured programming involves precise problem specification, top-down or stepwise program design, and block-structured or modular programs.

STTL See Transistor-Transistor Logic.

Subroutines improve program modularity and save memory space at a minimal cost in the overhead required to process the call/return sequence. See GOSUB.

Subroutine Passing parameters (also called arguments or data) makes information from one process or program available to another process or program. Similar to a football pass, except that one or more bytes of data replaces the football. Also, the receiver is a program. The sender may be a program or a person typing the data onto a command line to be "passed" to a program.

Syntax The rules governing proper construction of statements in a language. For programs, the rules include spelling and placement of keywords, spelling and type of data names, and number, type, and order of arguments. Punctuation rules are also usually part of syntax.

Syntax Check A check, performed by a program or person, to ensure that one or more statements in a programming language complies with all syntax rules of the language. A program may pass all syntax checks and still give an error message or erroneous results due to logic, data, or program flow problems.

Syntax Error Message BASIC. An error message from the Commodore 64 that appears when the computer reads a line and does not recognize the BASIC command. Even the slightest variation away from the format listed in the user's guide or reference guide will result in a syntax error. Be sure to include commas and parentheses where shown.

Syntax Error Message From the 1541 disk drive. An error message from the 1541 disk drive first indicates that the drive could not understand one of the commands sent to it. Specific syntax errors can be determined by reading the error number off the error channel (#15). They are as follows:

31 The drive does not understand the command sent. Make sure the command is in the correct format.

32 The command sent has exceeded the 58 characters allowable in a command.

33 The user has attempted to use pattern matching incorrectly in the LOAD or SAVE commands.

34 A file name is missing from a command or a colon is absent.

39 The disk does not recognize a command sent through the command channel (#15).

Synthy-64* Sound utility package that adds special commands to Commodore's BASIC language. These commands are executable in either the direct mode or in the program mode as long as the Synthy-64 interpreter resides in computer memory. The program lets the user enter music, using common notation (instead of PEEKs and POKEs in BASIC or addressing sound chip registers in Machine Code). For example: notes are entered by their alphabetic representation, followed by the octave number and the duration of the note. Key signature, flats, sharps, and rests are similarly entered. The volume of a note, as well as the tempo of the composition, can also be altered using single character commands. The Synthy-64 lets the

user exploit the full sound/synthesizer capability of the Commodore 64 without a lot of programming experience or knowledge. Abacus Software.

SYS A statement that transfers control of the microprocessor to a Machine language program located at the address specified. This statement is used in a BASIC program to jump to a Machine Code program somewhere in memory. The format is:

SYS <address>

This is the decimal address of a machine program in ROM or RAM. There must be a return at the end of the Machine Code to bring control back to the BASIC program.

SYSGEN CP/M. The SYSGEN program is available on disk in standard CP/M. It loads the system into memory and makes a copy of the system disk for safe keeping. See also CP/M Commands.

System A group of programs which accomplish some function (e.g., database management system), or a group of interconnected devices (e.g., turn the system off), or both taken together (e.g. a total accounting system).

Systems Software A software package is a group of computer programs, possibly including data files and documentation, which perform a function or group of related functions on the computer. These programs are called applications software when they perform tasks not directly serving the functioning of the computer. Examples would be a word processing package, an accounting package, etc. Systems software packages, on the other hand, facilitate the use of the machine; these include disk operating systems and program development packages.

T Codes. ASCII = 84, CBM ASCII = 84 or 212, HEX = 54. t—ASCII = 116, CBM ASCII = 84, HEX = 74. Screen code = 20 or 84. See CBM ASCII.

T An electrical network shaped like the letter "T". It has one input, one output, and one ground lead. It is used with resistors for attenuators and capacitors, and with inductors for filters. Also: True—a logical 1.

TAB BASIC function. Tabulates to position (n). The format is:

PRINT TAB<n>

<n> must be in the range 0 to 255.

If the current print position is already past space <n>, then TAB goes to position <n> on the next line. Space 1 is the leftmost position, and rightmost position is the defined WIDTH. TAB can only be used with PRINT and LPRINT.

Tab, Adhesive See Write-Protect.

Tabbing Moving the CRT cursor or printer head to a predefined column on the screen or paper, called a tab stop.

Table Look-up Method of converting one variable to a corresponding value, or verifying its accuracy by searching a list or table of entries for the known keyword or value. The corresponding values may then be extracted from corresponding positions in the table, much like looking up a name in the phone book to find the corresponding phone number.

Tachistoscope* Tests your memory by flashing words onto the screen and asking you to make an exact copy. Five speeds are available to increase your memory capabilities. Cassette. Micro-Ed.

TALK The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle input/output operations. By jumping to address FFB4, TALK commands a device on

the serial bus to act as a talker. Prior to using this routine the accumulator must be loaded with the device number. See KERNAL.

Talker The Commodore 64 utilizes a serial bus to connect to the 1541 disk drive and some printers. Since more than one device may be present on the serial bus at one time it is important that only one be transmitting data at a time. When data is INPUT# from a particular device, the Commodore 64 (using appropriate command signals and specific device number), sets that device as a talker. Only that device can put data onto the data lines until the Commodore 64 sends the unTALK command to it.

TAN BASIC Function. Gives the trigonometric tangent of (x). The format is:

<v> = TAN(x)

(x) is the angle in radians. Multiply by PI/180 to convert degrees to radians. PI = 3.141593

Terminal Mode A mode of operation of a general purpose computer such that its CRT and/or printer can be used as a terminal for another computer. Also called terminal emulation.

Terminal Pak Series* This hardware and software package is a terminal emulator that will convert your system into a terminal. You can select the baud rate compatible with the modem used. Micro Systems Development, Inc.

Terminal Program Software that allows the user to communicate with other computers through a modem. The program reads from the modem and prints characters typed in via the keyboard. This type of information exchange is called electronic communications. Many sophisticated terminal programs available for the Commodore 64 allow communication with other computers. These programs also provide upload/download facility and options to change modem and printer settings. Other features may also be available depending upon the specific product. Look under its product name for more details on specific products.

Test Data A programmer must insure that a program will correctly process all of the types of data for which it is intended. Samples of the data are prepared (test data) and the program is executed using this data (a test run). The program's outputs (reports, screen displays, files, etc.) are then verified to be as specified. An error in the processing logic of a program is called a "bug," hence the term "debug" and "bug-free."

There/Their/They're Helps children learn the correct uses of these troublesome "sound-alikes". Cassette. Micro-Ed.

Thimble Printer Prints fully-formed characters with a "thimble." The thimble is like a daisy wheel type element with the type petals bent up 90 degrees to form a cup or thimble shape.

TI\$ See Time\$.

Tic-Tac Math* Math program based on the old game. Helps elementary students sharpen their math skills. Cassette. Comm*Data Computer House.

Tic-Tac States* Great game to help youngsters learn states and their capitals offering various levels of difficulty. Cassette. Comm*Data Computer House.

Time\$ The Commodore 64 has an internal timer (jiffy clock) to synchronize activity within the system. On powering up the computer, the jiffy clock begins setting the variable TI\$ with six characters which correspond to the hour, minute, and second. These variables increase constantly as long as power is on. The user can refer to this variable any time to receive that data. The user can reset TI\$ by letting TI\$=000000. Using tape I/O alters TI\$. TI\$ is a reserved variable and can not be used for any other purpose. See Reserved Words.

Time Management* A scheduling and planning program for the Commodore 64. It records appointments/activities according to responsible person(s), dates, and categories. Reports may be organized and printed based on person, project, or activity. Allows browsing through or sorting reports according to beginning or ending dates. Comes with easy to follow documentation. TOTL Software, Inc.

Time Zones* Teaches elementary students about the time zones of the United States. Cassette. Micro-Ed.

Timeout Some operations performed by a computer or peripheral are given certain amount of time to be completed. If the operation has not been completed in that time a timeout occurs and the computer goes on with another operation. An error message may be shown. For example, when the Commodore 64 microprocessor tries to send information to the disk drive, it begins a series of operations to tell the disk drive that information is about to be sent. The disk drive has one millisecond to tell the microprocessor that it is ready to receive data (it grounds the data line). If the microprocessor doesn't hear from the disk drive then it sends to the screen a "device not present" signal and does not proceed with the data transmission.

Tiny BASIC Compiler* Allows you to increase the execution speed of your BASIC programs. While it does not permit all Commodore BASIC commands, it does permit all floating point and integer arithmetic. Abacus Software.

TKSA The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNAL. It is used to handle I/O operations. By jumping to address FF96, TKSA moves a secondary address from the accumulator to the serial bus. This routine is only used after completion of a TALK routine.

Tooth Invaders* As the protector of teeth you must fight tooth decay with all the products at your disposal. Commodore.

Totl.Label* Generates a mailing list. Allows the user to set up the format, deciding how many lines and how many characters per line, with a maximum of 254 characters per label. The first line can be used to sort, and can be masked

so it will not be printed. The printing instructions can be modified by the user to accommodate most types of labels and printers. The user can pattern match the first line to isolate a single label but the process must be continued manually each time to obtain all the matching labels. Also, the files are kept sequentially and are therefore rather slow. Cassette. TOTL. Software Inc.

Totl.Text* An inexpensive word processing package for the Commodore 64. It can be used with tape or disk and supports a wide variety of printers. The start-up options are menu-driven and easy to understand. The program is written in BASIC, so it is slower than word processors written in Machine language. However, the updated version of Totl.Text (version 2.6) is available with a Machine language program (Chickspeed) that speeds up loading and printing. The program supports many edit and format features as well as a few special print functions such as underline and enhanced and expanded text on certain printers. Text entering and editing is done in blocks of 255 characters, which makes processing slow. The function keys have specific edit functions which makes moving through text blocks easy. The documentation contains special instructions for modifying the main program as well as set-up routines for specific printers. The Totl.Text is capable of handling a variety of word processing tasks and is a good buy for novice users unfamiliar with word processing. It lacks, however, the sophistication and speed of many currently available quality word processors such as WordPro3 Plus or Easy Script. Disk or Cassette. TOTL. Software Inc.

To/Too/Two* Learn the proper grammatical uses of these homonyms. Cassette. Micro-Ed.

Touch Typing Tutor* Learn to type quickly and accurately at your own rate with this nineteen lesson program and twelve page manual. Disk or cassette. Taylormade Software.

Toystore* Teaches math in a toystore setting, by having students keep track of prices and figure out the balance after expenditures. Comm*Data Computer House.

TPA CP/M. Transient Program Area. This is the area of memory in CP/M allocated for loading user programs to be executed. A program often takes up more memory by occupying CCP and related areas used by various CP/M subroutines. When it finishes execution, command is given back to the CCP.

Track The 1541 disk drive saves data onto a disk in concentric rings called tracks. Each ring or track is divided into sections called sectors with each sector containing 256 bytes of information. Since the circumference of the tracks decreases toward the center there are fewer sectors per track in the middle of the disk than on the edge. There are 35 tracks per disk on the 1541 disk drive. When a disk is placed into the disk drive for the first time the tracks and sectors must be labeled or formatted, before the disk can be used to save data.

Track My Weight* Helps dieters keep track of their progress. Shows losses (and gains) with black and white charts to keep you on the road to your objectives. Powerbyte.

Trail West* Hang on to your units as long as you can during your two thousand mile journey to the California gold fields. Cassette. Micro-Ed.

Transient Program Area CP/M. See TPA.

Transistor An electronic device which can use one electrical signal to influence another. The two main uses of transistors are as amplifiers and switches. Used as an amplifier, a transistor uses the changes in a small signal to make large changes in a large signal. Used as a switch, the transistor opens or closes a circuit depending on the state of a controlling signal.

Transistor-Transistor Logic TTL. Logic circuits (AND, OR, NOT, etc.) that use transistors as switching units. TTL is the standard for microcomputers, because of its combination of speed, signal-to-noise ratio, and low-power designation. There are other logic designs that are superior in any one of these characteristics, but not in the combination of all three.

Tree Structure A collection of data organized so that each item is linked to one or more other items, creating a spreading network of linkage analogous to the branches of a tree. Genealogical data provide the classical model—each person has exactly one mother, but may have zero or more daughters. An example of data organized in this way might be the parts list of an airplane. The main entry is for the entire airplane. It is linked to the major components, such as wings, fuselage, tail. Wings, in turn, are linked to their smaller components, such as flaps, engine supports, engines, etc. Each of these can be further linked to smaller and smaller subassemblies, until individual parts such as nuts and bolts are reached.

Trek* An exciting version of the popular story has you commanding the starship and exploring new worlds. Cassette. Victory Software.

Trek* You are the commander and must pull your ship out of a very dangerous orbit. Cassette. Aardvark.

Triangles* Teaches triangle classification and description to junior high school students. Cassette. Comm*Data Computer House.

Triangular Waveform A triangular wave consists of a fundamental frequency and its odd harmonics, each in proportion determined by the reciprocal of the square of its harmonic number. Therefore the third harmonic is only 1/9th as loud, and the fifth harmonic is only 1/25th as loud. See also Harmonic.

Troublesome Pronouns* Students decide if pronouns are used correctly in twenty sentences. Includes performance rating. Datasette. Micro-Ed.

Truth Table • Type of Variable Names

Truth Table A table showing the logical value (true or false) of a compound logical expression, based on the logical value of the simple components of the expression.

Example:

A	B	A or B
T	T	T
T	F	T
F	T	T
F	F	F

This table reflects the definition of OR: A or B is true if and only if either A or B or both are true.

TSX Transfer Stack pointer to X register. An Assembly language instruction for the 6510 microprocessor that transfers the contents of the stack pointer into the X register. The stack pointer is left unchanged, but the sign flag bit and the zero flag bit can be altered by the word being transferred.

TTL See Transistor-Transistor Logic.

Tutti Frutti* Addition program for elementary students that can increase their ability to combine mixed numbers. Cassette. Micro-Ed.

Two-Minute Warning* Effectively teaches subtraction through playing football at the goal line with the clock running out. Cassette. MicroEd.

TXA Transfer X register to the Accumulator. An Assembly language instruction for the 6510 microprocessor that copies the X register contents into the accumulator. The X register is left unchanged but the sign and zero flag bits are affected by the transfer.

TXS Transfer X register to the Stack pointer. An Assembly language instruction for the 6510 microprocessor that copies the X register contents into the stack pointer. The X register is left unchanged, but the sign and zero flag bits altered.

TYA Transfer Y register to the Accumulator. An Assembly language instruction for the 6510 microprocessor that copies the contents of the Y register into the accumulator. The contents of the Y register are not altered, but the sign flag bit and zero flag bit are affected by the word being transferred.

TYPE CP/M. Displays the contents of the file specified on the screen. The format is:

TYPE<filename>

Type Declaration Character BASIC. Variable names can end with a type declaration character: \$ for string variables and % for integers from -32768 to +32767. Variables can be any length but only the first and second character are used. If a variable is not followed by a true declaration character, then it is assumed to be a floating point.

Type Mismatch An error message from the Commodore 64 that appears when a variable designated as either

numeric or string is equated with the wrong type. If you attempt to equate A="g" you are trying to make a floating point variable equal to a character. Be sure and use quotation marks around string data.

Types of Variable Names—Rules in BASIC

a) must start with a letter

b) can be any length but only the first two are considered.

c) cannot be a reserved word such as IF, ON, THEN, GOTO, etc. or a reserved word followed by a type declaration character (\$, %,), , !, #). See Reserved Words for a complete list.

d) end with a type declaration character: \$ if a string variable (for 0 to 255 letters, numbers, punctuation marks, and other characters); % for numeric integers (whole numbers from -32,768 to +32,767).

Also, the default value for the type of variable is Floating Point, so any variable name not ending in \$, %, or ! is automatically a numeric integer variable.

U Codes. ASCII = 85, CBM ASCII = 85 or 213, HEX = 55. u—ASCII = 117, CBM ASCII = 85, HEX = 75. Screen code = 21 or 85. See CBM ASCII.

UART Universal Asynchronous Receiver/Transmitter. A serial-to-parallel and parallel-to-serial converter. Usually a particular kind of Integrated Circuit used to interface a byte-parallel port to a bit-serial communications network or processor bus.

UCSD p-System An integrated program development system created by Kenneth Bowles at the University of California at San Diego. It includes an operating system, a full-screen text editor, and compilers for Pascal, FOR-

TRAN, and BASIC. Although originally developed to teach programming, it has been enhanced to provide the tools necessary for large-scale programming projects. The "p" refers to an imaginary "pseudo" computer. The system compilers produce "p" code, which is very compact, and which would run on a "pseudo" computer. An interpreter converts the "p" code into acceptable code for the actual computer on which the program is run. This makes the system very "portable," or easy to move between computers. Only a very small interpreter need be written for each computer on which the p-System runs. The p-System now works on over fifty different computers, with new interpreters being written all the time.

The system is highly interactive and consists of five main parts:

1) The full-screen Editor allows you to write both programs and text. It is easy to learn and to use. There is also an Advanced Screen Editor which has editing capabilities equal to sophisticated word processors.

2) The system Compilers convert the source code which you write into p-code. The Pascal compiler is integrated with the editor. When a syntax error occurs, you can return to the Editor at exactly the point where the error was detected. The Compiler error messages are accurate and informative.

3) The system Filer allows you to format disks, and to list, copy, rename, and remove files. Filenames may be up to sixteen characters long. The Filer will also check for errors on the disk and mark any bad areas located.

4) The system Linker automatically links together separately compiled "Units" of p-code. This allows you to build up libraries of useful procedures which can then be used by many different programs.

5) Finally, the interpreter converts the p-code to executable code. This is done automatically when the program is run.

The system is relatively easy to learn. Since it is highly integrated, it is easy to use. Although expensive, it is useful for beginners, as well as professional programmers. There is also a full range of application programs available which run under the p-System including spreadsheets, word processors, accounting programs, and a host of others. Several well-known programs were developed using the p-System, including VisiSchedule from VisiCorp and MBA from Context.

User Friendly Programs that have many prompts and instructions for easy use are called User Friendly. You will often be the only operator of programs you write, but if others will ever use your program, you need to give clear prompts (q.v.) for every item of input data and freeze the screen (q.v.) long enough for them to read or act on the information displayed. You should also provide clear error messages if anything is entered incorrectly or errors arise. This is often referred to as "human engineering"—making the program easy to use as well as technically correct.

There are several other guidelines for writing user friendly programs. If a complex series of data items has been typed in but some entries turn out to be invalid, the user should be able to re-enter only the bad items. Error messages should indicate not only that an entry is invalid, but also in just what way it is invalid and, if at all possible, some hints as to how to correct it (such as a list of possible correct values).

User Group A group or club focused on some aspect of computers. Some clubs direct their attention toward one particular computer—there are many Commodore User's Groups in the U.S. Other groups focus on a language (FORTH User's Group, Pascal User's Group, etc), on an Operating System (such as CP/M), on an area of application (accounting, education, science, or graphics) or other aspects of computing. Many magazines on computing carry lists of clubs/groups and report on their activities.

User groups provide a valuable opportunity for exchange of information on hardware, software, and applications. Often you can talk to someone who used a product you are considering buying. User group newsletters may also offer useful information. If you need a programmer or consultant, you may meet or hear about a good one at a User Group meeting.

User1 Disk Command. Similar to Block-Read command. When sent through the command channel the entire block specified in the command is moved from the disk to the channel specified. The Block-Read command on the other hand only moves that portion of the block that has data in it. The format is:

```
OPEN15,8,15 PRINT#15,"U1:"<channel>,<drive>,<track>,<block>
```

<channel> is a number from 2-14 previously opened in which data will be moved from disk.

<drive> is the disk drive number. 0 if only one.

<track> is the track number on disk of block to be read.

<block> is the sector number on disk of block to be read.

User2 Disk Command. When User2 is sent through command channel the result is similar to Block-Write command. One block of data is sent from the data channel to the specified block address on the disk. In Block-Write command the buffer pointer is also sent. Used for Random files. The format is:

```
OPEN15,8,15 PRINT#15,"U2:"<channel>,<drive>,<track>,<block>
```

<channel> is the channel number 2-14 previously opened through which data will be moved to disk.

<drive> is the disk drive number. 0 if only one drive.

<track> is the track number on disk where block will be moved.

<block> is the sector number on disk where block will be moved.

Users Guide* *The Commodore 64 User's Guide* comes with the Commodore 64. It is for the novice user and demonstrates some of the capabilities of the computer. It includes instructions for hooking up the system, an introduction to the BASIC 2.0 used on the Commodore 64 and some exercises in creating sprites and music. Commodore Business Machines and Howard W. Sams & Co., Inc.

Users Port Located in the rear of the Commodore 64, the Users port allows the computer to interface with a variety of peripheral devices including RS-232 devices. The bottom row of connectors through the port include 8 lines that can be accessed through address 56577 of memory. You can receive or send data through those lines to any peripheral that is voltage compatible. Each line can be programmed to send or receive data by programming the data direction register address 56579 with the appropriate value.

USR BASIC Command. The USR command enables the programmer to jump to a subroutine and enters a number into the floating point accumulator to be used by the subroutine. The address of the subroutine must be POKEd into address 785-786 before calling the USR command. The result of the USR command is the final value placed in the accumulator by the subroutine when it returns to BASIC. The format is:

```
USR(<n>)
```

<n> is the value of the argument to be stored into the accumulator.

USR functions differently in the 1541 Disk Drive BASIC. For more information see the USR-Disk manual.

USRT Universal Synchronous Receiver/Transmitter. A serial to parallel converter for high-speed communications.

Utilities The software used for routine tasks. Utilities facilitate or aid the operation and use of the computer for a number of different applications and uses. Examples of utilities are an editor, a sort, a debugger, and a file handler.

VAL BASIC Function. VAL returns the numerical value of the beginning of string x\$. The format is:

<v> = VAL(<x\$>)

<x\$> is a string expression.

The VAL function strips blanks, tabs, and line feeds from the argument string and selects numeric characters to determine the result. If the first characters of x\$ are not numeric, then VAL(<x\$>) will return 0. Refer also to STR\$.

Example:

```
PRINT VAL ("52 CASES")
```

```
52 READY
```

Validate Disk Command. The Validate command when sent through the command channel, re-organizes your disk by eliminating gaps and moving files to create larger sections of free space. It also eliminates any files that were opened but not properly closed. The command should not be used on disks that have random files as they will be lost. The format is:

```
OPEN15,8,15 PRINT#15,"VALIDATE"
```

VDU Video Display Unit. The British term for CRT.

VECTOR The name of a Machine language subroutine within the operating system of the Commodore 64 which is part of a group of subroutines referred to as the KERNEL. It is used to handle Input/Output operations. By jumping to address \$FF8D, VECTOR reads or sets the systems RAM vectors. If the carry bit of the accumulator is set, VECTOR reads the vectors in RAM and copies them into the memory pointed to by the address placed in the X and Y register. If the carry bit is 0, the vectors listed by the user at the address pointed to by the X and Y registers are copied into the system RAM vector.

Vector Display A CRT which moves the electron beam randomly to trace figures on the screen. Contrast this with a raster display, which sweeps the beam through a fixed pattern, building up an image with a matrix of points. Vector displays are used in many arcade games.

VERIFY BASIC Command. Can be used in program mode or direct mode. The command compares the contents of a BASIC program file on tape or disk with the program that is currently in memory. It is most often used just after the SAVE command to make sure that the program was stored correctly. The format is:

VERIFY <name>,[<dev>]

<name> is the name of the file on cassette or disk to be compared with the file in memory.

<dev> is the device number of the device where the file resides. Eight for disk. If the device number is left out the system assumes device 1 for cassette.

VIC 20* An inexpensive personal color-output computer from Commodore Business Machines.

VI-Check* Helps you manage your checkbook. Keeps a current balance, catches duplicate entries, and lists transactions, accounts, etc. United Microware Industries.

VIC-II The VIC-II (MOS 6566 Video Interface Controller) chip is a color video controller device that is responsible for the video output of the Commodore 64 through its forty-seven control registers. The chip is located at address 53248 thru 53294 (HEX \$D000 to \$D02E). The registers are accessed via a standard 8 bit microprocessor bus. The chip is capable of accessing 16K bytes of memory for its display information. It operates in two modes: the standard character mode and the bit-map mode (standard and multicolor). Its most noteworthy feature is the sprite or (Moveable Object Block) MOB. The VIC chip controls the position, color and the Bit-Mapped description of the sprite. It can be programmed to simulate animation of sprites. Other features of the VIC chip include scrolling, screen blanking, and the Light-Pen registers. See also Sprites, Graphics, Bit-Map Mode, Standard Character Mode, Scrolling.

Vicmodem* A direct connect modem which is directly compatible with the Vic 20 and the Commodore 64. The device utilizes EIA standard RS-232C handshaking signals and is compatible with Bell 103 type modems. The modem is a hardware device to connect your telephone with the computer. It is inserted into the User Port of the Commodore 64 and contains a female socket in which the male end of a modular phone (the part that inserts into the handset) is inserted.

To use the Vicmodem, a program must be running that will open a channel to the device and establish the proper Baud rate, Duplex, parity, word length, and stop bits. These parameters depend on the Computer you are trying to access. Once the parameters are known they are entered into the Control Register and Command Register (Address 665-666) either during an open statement or with the POKE command.

When opening an RS-232 channel, two buffers are created in which data is sent or received. The computer will establish handshaking signals so that data is not lost while trying to send when the other computer is also sending. See RS-232. Commodore.

VIController* A home control system that can maintain lights and appliances, has manual and time control, and uses BSR remote switches. Genesis Computer Corp.

W Codes. ASCII = 87, CBM ASCII = 87 or 215, HEX = 57. w—ASCII = 119, CBM ASCII = 87, HEX = 77. Screen code = 23 or 87. See CBM ASCII.

Wafer A slice of a silicon ingot on which integrated circuits are fabricated. After testing and fabrication, the wafer is cut up into individual circuits called dice or chips. The dice are packaged, sorted, and tested before being used as finished IC components.

WAIT BASIC Statement. Suspends program execution while monitoring the status of a specific address in memory. The format is:

WAIT <add>,<n>[,<m>]

<add> refers to the address in memory and may be in the range 0 to 65535.

<n><m> are integer expressions in the range 0 to 255.

WAIT suspends execution until a specified machine input port develops a specified bit pattern. The data read at the port is XORed with the integer expression <m> and then ANDed with <n>. If the result is zero, BASIC loops back and reads the data at the port again. If the result is nonzero, execution continues with the next statement. If <m> is left out, it is assumed to be zero.

The WAIT statement allows you to test one or more bit positions on an input port. You can test the bit position for either a 1 or a 0. The bit positions to be tested are specified by setting 1's in those positions in <n>. If you do not specify <m>, the input port bits are tested for 1's. If you do specify <m>, a 1 in any bit position in <m> (for which there is a 1 bit in <n>) causes WAIT to test for a 0 for that input bit.

When executed, the WAIT statement loops test those input bits specified by 1's in <n>. If any one of those bits is 1 (or 0 if the corresponding bit in <m> is 1), then the program continues with the next statement. Thus WAIT

does not wait for an entire pattern of bits to appear, but only for one of them to occur.

It is possible to enter an infinite loop with the WAIT statement. You can execute a RunStop/Restore to exit the loop.

Wait State A micro-cycle or internal state entered by an MPU when a synchronizing signal is not present. It is used to synchronize a fast processor with a slower memory.

Word Processor A program that allows the user to create and edit text files on the screen and print a user-formatted hard copy. Word processors have widespread use in business as well as home for preparing letters, reports, contracts, etc. They vary in the features that they incorporate to facilitate editing and formatting of the documents. In choosing a word processor, it is important to know the features that a good word processor should have. (see Word Processors). For a listing of the word processors reviewed in this book, see Word Processors.

Word Processors—Salient Features Following is a brief discussion of the features available in some of the good word processors for the Commodore 64.

DOCUMENTATION includes step training exercises that

take the user through the various steps of word processing, from start-up options to creating, editing, saving, and printing text files. These exercises may also include a "special applications" training section that deals with applications such as mail merge and filling in forms.

START-UP OPTIONS are the initial options presented to the user in a menu-driven format. They include the display format (text width 40 columns or more); disk or tape options (for serious word processing, disks are indispensable); setting printer type (a good word processor will support a variety of different types of printers; dot matrix and letter-quality); and setting the most visually pleasant background/text colors.

TEXT EDITING AND FORMATTING is the main body of a word processing program. Numerous features are included to manipulate text while in the entering/editing mode. These features include setting tabs; vertical and horizontal scrolling; inserting and deleting words, lines, or paragraphs; and rearranging and transferring blocks of text from one location to another. Formatting and outputting the text involves setting margins, page length, text length, vertical positioning, line spacing, headers, footers, and automatic page numbering. Options are included for margin release at the beginning of paragraphs, left or right justification, or centering paragraphs.

FILE HANDLING includes saving or loading files on disk or tape. The files may be saved as "fill files," "ranged blocks" or as "linked files." The Load feature may allow "appending," "overwriting" or "merging" text files. These features have applications in linking a number of files on disk (to process large documents) as well as mail merge (which provides an easy way to personalize standard letters for a large number of people). Other features include accessing disk operations while in the program mode, which allows the use of many file manipulation features that are available with the Commodore (VIC 1541) disk drive.

SPECIAL FEATURES are for advanced users, and allow them to use the word processor with other programs such as terminal emulator programs and databases. Other special features include programmable characters and special codes that support specific print features (in some printers) such as "italics," "superscripts," "subscripts," "underlining," "bold face," and double-width character font.

Word Search* After choosing and entering ten words, the elementary student must try to find them as they reappear in a grid of scrambled letters. Performance review follows. Cassette. Micro-Ed.

WordPro3 Plus/64* A versatile word processor for the Commodore 64. It is 100% Machine language for speed and efficiency and supports a variety of dot-matrix and letter quality printers. The documentation includes step by step instructions on getting started and training exercises for editing, formatting, and printing text.

The system disk comes with a sample letter that demonstrates program features. In the word processing

mode, a status line is displayed on top of the screen that guides the user through the operating modes. One of the unique features available on WordPro3 is the extra text mode (which is like having an extra screen). The user can switch between the main text and the extra text using the control key (<control> x <CR>) and create an alternate memory area to store frequently used phrases, variable blocks, mailing addresses, etc. The amount of space available in this mode is established by the user during start-up options. The feature provides special facilities to advanced users such as appending extra text, variable blocks, or groups of lines to create form letters and reports. It can also be used to store outlines of reports that are being created in the main text. Other features of WordPro3 Plus include full editing and formatting capability, advanced file handling (linking files, global search/replace, and output operations), and special characters for accessing special printer functions. The manual includes a programmer's section that discusses the use of the input/output features of WordPro3 Plus with mailing lists and terminal programs. Disk commands are also accessible in the program mode. Professional Software.

Words, Reserved BASIC. Reserved words have particular meanings in BASIC and are used for commands, statements, function, and operator names. These words cannot be used as variable names and variable names cannot be reserved words followed by a type declaration character (\$, %). If you accidentally use one of the reserved words, you may see an error message or have strange results when you execute the program. See also Debug or Test a Program, Reserved Words.

Words in Context Spelling Series* An educational testing series which reinforces regular classroom instruction. There are 180 lessons for grades two through six. The student chooses the lesson he wants to study. The program displays 10 words which can be recalled to the screen at any time. Now, here's the problem: A sentence that is missing a word is shown on the screen. The student's job is to fill in the missing word with the correct choice of one of the ten words displayed on the screen. The student's performance is rated. Elementary level. Cassette. Micro-Ed.

Wordspot* Distinguish valid words from the first letters which come from the left and the last letters which come from the right. For seven to ten year-olds. Cassette. Comm*Data Computer House.

Wordtalk 64* This package is a telephone communication program able to link the Commodore 64 to almost any other computer via a telephone modem. Data, documents, letters, and messages can be sent and received. Connections with UPI news, the Dow Jones, Compuserve, and other services are possible. UMI

Working With Basic Addition Facts* A series of addition problems that classifies responses by time needed to solve the problem, answers given by the computer, and number of correct answers. Cassette. MicroEd.

Working With Basic Multiplication Facts* A series of

multiplication tests to help elementary students increase math skills. Cassette. MicroEd.

Workspace An area of memory allocated for working storage.

WPM Words Per Minute

WRITE Output data from memory. Memory is any device which can store information and allow it to be retrieved when needed. The Commodore 64 relies primarily on random access memory (RAM), read-only memory (ROM), and disks. ROM and RAM together make up the internal memory or main memory of the Commodore 64, or any other computer.

External memory is stored on cassette, disk, and hard disk, and involves mechanical motion to retrieve data. These are hundreds or thousands of times slower than internal memory. Data in internal memory is immediately available to programs for processing. Data in external memory must be copied into internal memory, processed, then copied back out to external memory.

If data has been created, it can be written out to external memory without a READ first. If data read in from external memory has not been modified, there is no need to write it back out since the original copy is still there.

Write Error If there is an inconsistency between the data that is written onto disk and the data that should have been written onto disk this message appears. There are two specific write errors shown below.

25 appears if the data written on disk does not equate with the data in Disk Ram where it was just written from.

28 appears if a synchronous mark does not appear at the beginning of sector. When writing to disk, the drive attempts to read these sync marks. The problem is a bad disk, an unformatted disk, or a hardware problem.

Write File Open An error message from the 1541 disk drive incurred when a write file that has not been closed is opened for reading.

Write Protection On This message appears if you try to write to a write-protected disk. Either the user has an adhesive tab over the write-protect notch or there is a problem with the write-protect system.

Write-Protect Describes the act of preventing the writing of information onto a storage medium. Floppy disk jackets often have adhesive tabs which can be removed or placed on the disk to write-protect the disk by disabling the disk drive's write circuitry. Cassettes have a similar plastic break-out tab.

Writer's Assistant, The* This word processor features a menu-driven format and easy-to-follow tutorial style documentation. The system disk consists of a series of BASIC programs that perform the functions of the word processor. The programs are automatically loaded from the main program when the user selects the appropriate option. Several files are included in the program disk to guide the user through the special features of the word

processor. The program's main menu allows the user to set up printer configuration, access disk commands, enter/edit text, and print a specified document. A secondary menu is available in the word processing mode that allows text file manipulations. A help command can be accessed at any time to obtain an explanation of the function keys. The program's menu-driven design is very useful for beginners interested in word processing. Rainbow Computer Corporation.

Z-80 Video Pak Includes a cartridge that inserts into the expansion port, an operating system compatible with CP/M 2.2, and the cables necessary for connecting the video output from the Commodore 64 to the video Pak. The output generated by the Video Pak formats the screen into an 80 column by 25 line display. Most standard word processing programs such as Wordpro or Easy Script can not be run with the video pak. A word processor from Data 20 for the 80 column display is available. Some handy features come with the Video Pak, including a screen dump feature that lets the user print what appears on the screen. Portions of a line beyond the cursor can be deleted by pressing a single function key. The screen can be returned to a 40 column mode with a function key. There is a terminal emulator mode that allows easy configuration of the Commodore for data transmission. The documentation is very weak and presumes you have some experience with CP/M. A HELP command does allow you to view available CP/M commands. CP/M based programs that are in Commodore disk format can be executed with this system. Data 20.

Zero Flag Bit See Status Register.

Zero Page The Commodore 64 can reference any of the 64K addresses using two bytes. The first 256 memory locations can be referenced using only one byte. Therefore these first 256 bytes (or zero page) can be used in Machine Code instructions more efficiently than those that follow.

Zero Page Addressing Mode See Addressing Modes.

Zone To leave space on the print line between items, put a double comma(,,) in the print listing.

Example:

PRINT A,,B

This would print A in print zone 1, nothing in print zone 2 and put B in print zone 3, (column 29). See also Zones and PRINT Lines.

Zones On the printer line, each group of ten spaces across the print line is called a print zone. A comma (,) in a PRINT list of items means "start printing the following item at the start of the next print zone." Contrast this with the semi-colon (;), which means the next item is to print immediately after this one, without even a single space between. The print zones begin in columns 1, 10, 20, 30, 40, 50, 60, 70, and 80.

- 8087 Chip** Numeric data co-processor for the 8086 and the 8088. Implements proposed IEEE floating point standard.
- 8088** 16 bit processor from Intel. The 8088 is a slightly stripped-down version of Intel's original 1978 8086. The 8088 differs from the 8086 in the following ways:
- 1)The 8088 uses an 8 bit data bus, as opposed to the 16 bit data bus of the 8086. The 8088 will need about twice as many memory cycles to fetch the same amount of data as the 8086.
 - 2)The instruction "fetch-ahead" queue of the 8088 is 4 bytes, vs 6 bytes in the 8086. The 8088 must wait for instructions to be fetched from memory more often than the 8086.
- The 8088 is thus a 16 bit processor internally but with an 8 bit bus structure. Other than this, the 8088 and 8086 are the

same. Even at the Assembly language and Machine Code level, they are interchangeable to the programmer.

The 8086/8088 processors have built in provision for being paired with a co-processor which can perform certain functions faster than the main processor. The main example so far is the 8087, which is specialized for floating point operations. When working with the 8087, the 8088 passes all floating point arithmetic to the 8087 and waits for it to signal completion. The result is faster execution (up to 100 times as fast) for programs with extensive floating point calculations.

The 8086/8088 processor can assemble programs for the earlier 8008 and 8080 processors, but the object codes are not compatible.
